Abstract: This Supplemental Draft Environmental Impact Statement (EIS) is a public document that discloses the direct, indirect, and cumulative effects of the proposed action and alternative actions for the Stibnite Gold Project. This document follows the format established in the Council on Environmental Quality (CEQ) regulations (40 Code of Federal Regulations [CFR] Parts 1500–1508). It includes a discussion of the purpose and need for the proposal; alternatives to the proposal; the physical, biological, social, and economic impacts of the proposed action and alternatives; and a listing of agencies and persons consulted. The document tiers to and incorporates by reference material in the Final EIS and record of decision (ROD) for the 2003 Land and Resource Management Plan (Forest Plan), as amended for the Payette National Forest, and the Final EIS and ROD for the 2010 Boise Forest Plan.

Submit Written Comments To: Linda Jackson, Payette Forest Supervisor
Stibnite Gold Project
500 N. Mission Street, Building 2, McCall, Idaho 83638

Submit Electronic Comments To: https://www.fs.usda.gov/project/?project=50516

Please state “Stibnite Gold Project” in the subject line when providing electronic comments, or on the envelope when replying by mail. Electronic comments must be submitted in a common digital format such as plain text (.txt), rich text format (.rtf), Word (.doc, .docx) or PDF (.pdf).

Project Website: https://www.fs.usda.gov/project/?project=50516

In accordance with Federal civil rights law and U.S. Department of Agriculture (USDA) civil rights regulations and policies, the USDA, its Agencies, offices, and employees, and institutions participating in or administering USDA programs are prohibited from discriminating based on race, color, national origin, religion, sex, gender identity (including gender expression), sexual orientation, disability, age, marital status, family/parental status, income derived from a public assistance program, political beliefs, or reprisal or retaliation for prior civil rights activity, in any program or activity conducted or funded by USDA (not all bases apply to all programs). Remedies and complaint filing deadlines vary by program or incident. Persons with disabilities who require alternative means of communication for program information (e.g., Braille, large print, audiotape, American Sign Language, etc.) should contact the responsible Agency or USDA’s TARGET Center at (202) 720-2600 (voice and TTY) or contact USDA through the Federal Relay Service at (800) 877-8339. Additionally, program information may be made available in languages other than English. To file a program discrimination complaint, complete the USDA Program Discrimination Complaint Form, AD-3027, found online at http://www.ascr.usda.gov/complaint_filing_cust.html and at any USDA office or write a letter addressed to USDA and provide in the letter all of the information requested in the form. To request a copy of the complaint form, call (866) 632-9992. Submit your completed form or letter to USDA by: (1) mail: U.S. Department of Agriculture Office of the Assistant Secretary for Civil Rights 1400 Independence Avenue, SW Washington, D.C. 20250-9410; (2) fax: (202) 690-7442; or (3) email: program.intake@usda.gov. USDA is an equal opportunity provider, employer, and lender.
Executive Summary

Introduction

The Stibnite Gold Project (SGP) proposes mine operations on federal, state, and private lands located in Valley County, Idaho. This supplemental draft Environmental Impact Statement (SDEIS) was prepared in response to a revised Plan of Restoration and Operations (Plan) for the SGP. The Forest Service received the original SGP Plan in 2016, (Midas Gold Idaho, Inc. [Midas Gold] 2016a) for review and approval in accordance with regulations at 36 Code of Federal Regulations (CFR) 228 Subpart A. A revised Plan was submitted to the Forest Service in 2019 (Brown and Caldwell 2019a). A draft EIS (DEIS) evaluating five alternatives based on the revised Plan was released by the Forest Service in August 2020. A further modified Plan was initially submitted by Midas Gold in December 2020 with a revised submittal in October of 2021 (Perpetua 2021a). Midas Gold changed their name to Perpetua Resources Ltd (Perpetua) in February 2021. In consideration of the modified Plan, the Forest Service determined that a SDEIS is warranted and based on further analysis, two of the previous action alternatives (August 2020 DEIS Alternatives 1 and 3) were eliminated from further consideration. The SDEIS therefore evaluates the Proposed Action, the Johnson Creek Route Alternative, and the No Action Alternative.

The Forest Service, specifically the Payette National Forest, is the lead agency in the preparation of this SDEIS (40 CFR 1501.5). The Boise National Forest is participating, as well as cooperating agencies including the U.S. Army Corps of Engineers (USACE), U.S. Environmental Protection Agency (EPA), Idaho Governor’s Office of Energy and Mineral Resources (OEMR), Idaho Department of Lands (IDL), Idaho Department of Environmental Quality (IDEQ), and Valley County, Idaho.

Purpose and Need

The Forest Service’s purpose is to consider approval of Perpetua’s proposed use of the surface of NFS lands in connection with operations authorized by the U.S. mining law as first described in the Plan submitted September 2016, then refined in 2019 (Brown and Caldwell 2019a), and further modified in 2021 as the 2021 Modified Mine Plan (MMP; Perpetua 2021a). The Forest Service’s need for action is established by the agency’s responsibility under the Locatable Minerals regulations at 36 CFR Part 228, Subpart A and the General Mining Law of 1872 (Mining Law), as amended (30 U.S.C. 22 et seq.). The need for action is to:

- Consider approval of Perpetua’s 2021 MMP for development of the SGP to mine gold, silver, and antimony deposits that, where feasible, would minimize adverse environmental impacts on NFS surface resources; and ensure that measures are included that provide for mitigation of environmental impacts and reclamation of the NFS surface disturbance.

Perpetua’s 2021 MMP includes the discharge of dredge and fill material into waters of the U.S. (WOTUS), including wetlands. Accordingly, the USACE, pursuant to Section 404 of the Clean Water Act (CWA), will review the SGP and render a decision to either issue, issue with special condition, or deny a permit for the Project. As a cooperating agency the USACE intends to use this EIS process and document for evaluating compliance with its responsibilities under NEPA and the CWA Section 404(b)(1) Guidelines. As part of its review, the USACE is required by the CWA to independently
consider and express the activity’s underlying purpose and need from Perpetua’s (the applicant) and the public’s perspectives (33 CFR 325).

From the USACE’s perspective, the basic purpose for the SGP is to extract gold, silver, and antimony from ore. Under the CWA Section 404(b)(1) Guidelines (40 CFR 230), the USACE uses the basic project purpose to determine if a project is “water dependent.” A project is water dependent if it must be located in, or be close to, a special aquatic site, including wetlands, to fulfill its basic purpose. The USACE has determined that mining gold, silver, and antimony ore is not a water-dependent activity. The overall project purpose is to mine gold, silver, and antimony from ore deposits associated with the SGP. This overall project purpose will be used for evaluating practicable alternatives under the 404(b)(1) guidelines. The 404(b)(1) analysis will be completed by the USACE following the receipt of public comments on both this SDEIS and Perpetua’s application for a Department of the Army (DA) permit for the SGP.

Federal Decision Framework
The U.S. mining laws (30 U.S.C. 21-54) govern exploration and development of mineral resources on public lands. Locatable minerals operations on NFS lands are subject to regulations found at 36 CFR 228 subpart A. Locatable mineral operations are to be conducted so as to, where feasible, minimize adverse environmental impacts on National Forest surface resources (36 CFR 228.8). In prospecting, locating, and developing the mineral resources, all persons must comply with the rules and regulations covering the National Forests (16 U.S.C. 478). All functions, work, and activities on NFS lands in connection with prospecting, exploration, development, mining, or processing of mineral resources and all uses reasonably incident thereto, including roads that are constructed and maintained in connection with development and mining of mineral resources, are operations authorized by the U.S. mining laws (36 CFR 228.3(a)).

The Forest Service is the lead agency in the preparation of this document (40 CFR Part 1501.5). The USACE is a federal cooperating agency with decisions to be made based on this environmental analysis consistent with the NEPA. Other federal, state, and local agencies are also participating in this review as cooperating agencies.

The Payette Forest Supervisor, as the responsible official acting on behalf of the lead agency, has determined that preparation of an EIS is required because approving the 2021 MMP may have significant impacts on the human environment (40 CFR Part 1501). The Payette Forest Supervisor will make the following decisions:

- Whether to approve the 2021 MMP as submitted, or any alternative considered in detail in the final EIS (FEIS).
- Whether to amend¹ the Payette Forest Plan (FEIS and Record of Decision for the Revised Payette Land and Resource Management Plan, 2003 is incorporated by reference). One or more project-specific amendments to the forest plan would be required.

¹ Forest plan amendments are evaluated under the 2012 Planning Rule per 36 CFR Part 219.17(b)(2), which requires all forest plan amendments initiated after May 9, 2012, to use the 2012 Planning Rule.
The Boise Forest Supervisor will make the following decisions:

- Whether to amend the Boise Forest Plan (FEIS and Record of Decision for Revised Boise Land and Resource Management Plan, 2010 is incorporated by reference). One or more project-specific amendments to the forest plan would be required.

The Payette and Boise Forest Plans provide direction relevant to the 2021 MMP and its alternatives through forest-wide plan components and management areas. Management Areas (MAs) in the SGP area include the following:

**Payette National Forest**

- Management Area 13 Big Creek/Stibnite

**Boise National Forest**

- Management Area 17 North Fork Payette River
- Management Area 19 Warm Lake
- Management Area 20 Upper Johnson Creek
- Management Area 21 Lower Johnson Creek

Amendments to the Payette and Boise Forest Plans would be required to approve the 2021 MMP or the Johnson Creek Route Alternative. A forest plan may be amended at any time. The responsible officials (Boise and Payette Forest Supervisors) have the discretion to determine whether and how to amend the plan(s) and to determine the scope and scale of any amendment. A plan amendment is required to add, modify, or remove one or more plan components. The proposed removal of the below identified forest plan Standards would be one-time amendments to the current forest plans and would be project-specific and apply only to the SGP. These amendments would be made according to the 2012 Planning Rule (36 CFR Part 219.13) and will comply with the direction in both forest plans relating to Standards.

Opportunities for public participation and notification regarding the forest plan amendments will be combined with the public participation and notification processes used for project planning at 36 CFR Part 218 for this EIS (36 CFR 219.13). The project-specific amendments for this Project may have effects directly related to 2012 planning rule’s substantive requirements regarding sustainability (Section 219.8), plant and animal community diversity and persistence of native species (Section 219.9), multiple use (Section 219.10), timber (Section 219.11), and others.

Forest Plan amendments, summarized in Table ES-1, could be needed in four resource topics, depending on the action alternative selected, to allow the SGP to be consistent with the Payette and Boise Forest Plans.
The USACE, under Section 404 of the CWA, will review the Project and either issue, issue with special conditions or deny a permit for the Project. The USACE regulates the discharge of dredged and/or fill material into WOTUS, including wetlands (Section 404 of the CWA). The 2021 MMP would place dredged and/or fill material in WOTUS as regulated under Section 404 of the CWA. A CWA Section 404 permit is required for the discharge of dredged and/or fill material into jurisdictional WOTUS (33 CFR Part 323).
In accordance with the CWA Section 404(b)(1) guidelines (40 CFR Part 230), the USACE may permit only the least environmentally damaging practicable alternative while considering cost, logistics, and technology. The USACE has determined that potentially jurisdictional WOTUS, including wetlands, are present that may be impacted by the Project. These waters are described in the “Wetlands and Riparian Resources” section of Chapter 3.

**Proposed Action (2021 MMP)**

The revised Plan submitted by Perpetua in October 2021 is considered to be the Proposed Action, also known as the 2021 MMP, and would consist of mine operations, including an open pit hard rock mine and associated processing facilities, located within Valley County in central Idaho on federal, state, and private lands (Figure ES-1). The SGP would produce gold and silver doré, and antimony concentrate, for commercial sale by Perpetua. The SGP would have a life (construction, operation, closure, and reclamation), not including post-reclamation monitoring, of approximately 20 years, with active mining and ore processing occurring over approximately 15 years.

The following mine components would be common to the two action alternatives:

- Mine pit locations, areal extents, and mining and backfilling methods
- Transportation on existing and proposed roads
- Pit dewatering, surface water management, and water treatment
- Ore processing
- Lime generation
- Tailings storage facility (TSF) construction and operation methods
- TSF Buttress construction methods
- Water supply needs and uses
- Management of mine impacted water and stormwater runoff
- Stibnite Gold Logistics Facility (SGLF)
- A road maintenance facility
- Surface and underground exploration
- Worker housing facility

For access, the 2021 MMP would utilize Warm Lake Road, Johnson Creek Road, and Stibnite Road during construction of the proposed Burntlog Route; then once constructed, the Burntlog Route would be the primary access route during operations and reclamation.
Johnson Creek Route Alternative
The Johnson Creek Route Alternative was developed to evaluate potential reductions in impacts to various resources caused by the Burntlog Route. The mining portion of this alternative would be the same as under the 2021 MMP. Therefore, the primary focus of the Johnson Creek Route Alternative would be using an existing route, with improvements, for mine access during operations and reclamation instead of the Burntlog Route that requires new road construction in Inventoried Roadless Areas (IRAs). The Johnson Creek Route Alternative would require extensive upgrades to both Johnson Creek Road and Stibnite Road. The construction schedule for upgrading the roads and construction of the SGP would increase from 3 years to 5 years under this action alternative.

No Action Alternative
The No Action Alternative provides an environmental baseline for comparison of the action alternatives. Under the No Action Alternative, the mining, ore processing, and related activities under the 2021 MMP or the Johnson Creek Route Alternative would not take place. In addition, certain legacy and existing mining impacts would be addressed as directed in the 2021 Administrative Settlement Agreement and Order on Consent, including installation of stream diversion ditches designed to avoid contact of water with sources of contamination and removal of development rock and tailings currently impacting water quality. However, existing and approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue and Perpetua would not be precluded from subsequently submitting another plan of operations pursuant to the General Mining Law of 1872.

Agency Preferred Alternative
Following their review of the environmental impacts as discussed in the SDEIS, the Forest Service has identified the 2021 MMP as their Preferred Alternative for the SGP because this alternative:

- Incorporates water management and closure activities to reduce the duration of long-term water treatment requirements.
- Incorporates measures to manage stream temperatures.
- Reduces the potential for impacts associated with access, transportation, and hazardous materials on Johnson Creek and the East Fork SFSR downstream of the Operations Area Boundary.

The Agency Preferred Alternative would reasonably accomplish the purpose and need for the federal action, while giving consideration to environmental, economic, and technical factors.

Environmental Impacts

Geologic Resources and Geotechnical Hazards

**Extraction of Mineral Resources**
Geologic studies by Perpetua have reported approximately 132.3 million tons of measured and indicated ore resource (including historical tailings) for the SGP property with another 36.2 million tons of inferred ore. Under the 2021 MMP, approximately 280 million tons of development rock and 112 million tons of ore would be mined. About 3.2 million tons of historical Bradley tailings "ore" would also be removed and reprocessed. Total ore processed would be 115.2 million tons. The extraction of mineral resources would be the same for the 2021 MMP and the Johnson Creek Route Alternative.

* Associated with 2021 MMP only
** Associated with Johnson Creek Route Alternative only

Note:
The McCall - Stibnite Road (CR 50-412) consists of Lick Creek Road, East Fork South Fork Salmon River Road (East Fork Road) and Stibnite Road.
The contained metal content in the 2021 proven and probable mineral reserve of the property is approximately 4.819 million ounces of gold, 6.431 million ounces of silver, and 148.686 million pounds of antimony. From the total ore currently planned to be mined the SGP is estimated to recover, over 15 years of mill production, 4.238 million ounces of gold, 1.710 million ounces of silver, and 115.342 million pounds of antimony.

**Topography**

Mining under the 2021 MMP would result in expanded open pits at the Yellow Pine and West End deposits and a new open pit at the Hangar Flats deposit. Each of these pits would result in highwalls developed in rock that would permanently remain after mining. These highwalls are geotechnically designed to be stable and would be permanent features imposed on the topography of the site. Each of these pits would also be backfilled with development rock to a certain degree which would bury certain portions of the open pits and their highwalls.

Other major changes to local topography would include the proposed TSF and the TSF Buttress. Smaller changes to topography would occur due to engineered cuts and fills at constructed haul roads, processing facilities, and ancillary facilities. The Burntlog Route access road would also be constructed with engineered cuts and fills that would change the topography along its route. The effects of the mine operations on topography would be the same for the 2021 MMP and the Johnson Creek Route Alternative. Topographic impacts from construction of the Johnson Creek Route would be different than the 2021 MMP, but when considered in total along with the other mining related topographic impacts, the differences in total project impacts to topography between the two road alignments would not be significant.

**Geotechnical Stability**

Some SGP facilities would have exposure to potential geotechnical impacts from existing landslides, rockfalls, and avalanche paths. SGP facilities to be located in the vicinity of these hazards would include designs and operational procedures to reduce risk to workers and operations.

Geotechnical stability of the SGP facilities would be ensured by practices for design, construction, and operation of the facilities. Studies have been conducted to characterize the geologic conditions of the foundation areas of these facilities and these characteristics have been incorporated into the designs of the facilities.

The designs of major earth fills such as the TSF and TSF Buttress have incorporated slope stability analyses including the potential effects of earthquakes. Impacts from earthquakes on these and other SGP facilities would be minimized by incorporation of existing geotechnical design standards and building code standards, as well as construction quality control, operations and maintenance, and surveillance.

The hazards from mass wasting events along the Johnson Creek Route would be increased compared to the Burntlog Route. There are more areas of landslides and rockfalls along the Johnson Creek Route (45) than there are along the Burntlog Route (26). Potential avalanche paths crossed by the Johnson Creek Route (94) are more numerous than the Burntlog Route (38) and are more significant in size than along the Burntlog Route. The increased numbers of mass wasting hazards along the Johnson Creek Route
would be expected to result in an increased number of temporary road closures and possible accidents involving vehicles than the Burntlog Route.

**Air Quality**

The air quality analysis conducted for the SGP examined impacts on defined geographic regions that relate to different types of modeling processes. First, a “near field” region surrounding the SGP was examined using air dispersion models to quantify pollutant concentrations and related impacts.

Second, a much larger “far-field” region was defined that encompassed more-distant Class I areas, wilderness areas, and tribal lands. In these areas, specialized air quality modeling tools were applied to evaluate the combined effects of dispersion, deposition, and chemical transformations in the atmosphere. The models assessed SGP source contributions to regional haze, nitrogen deposition, and sulfur deposition.

**Extent of Pollutant Concentrations and Deposition**

Dispersion modeling based on a representative mine operating scenario and the year with highest estimated aggregated air emissions, demonstrated that pollutant concentrations at the Operations Area Boundary would not exceed the National Ambient Air Quality Standards (NAAQS). This conclusion applies for both action alternatives. Deposition of mercury (Hg), and nitrogen and sulfur species were predicted to be less than Significant Impact Levels (SILs). A supplemental Hazardous Air Pollutants (HAPs) modeling analysis was also completed for all sources and compliance with the state acceptable ambient concentrations was demonstrated.

The SGP emission sources for the Johnson Creek Route Alternative are essentially the same as the 2021 MMP. Under the No Action Alternative, the SGP would not be constructed, so the air quality in the area would be unaffected by the 2021 MMP.

**Type and Volume of Air Pollutants Emitted**

To characterize the highest anticipated annual emission levels for purposes of conservative air quality impact analysis, a complete emission inventory was compiled for each year from construction through Life of Mine (LOM) Year 18. The year of peak mine throughput, LOM Year 6, was found to have the highest aggregate pollutant emissions, including haze precursors, airborne dust, and HAPs.

**Criteria Air Pollutant Ambient Concentrations Outside the Operations Area Boundary**

Dispersion modeling based on the 2021 MMP inventory demonstrated that impacts would not exceed NAAQS outside the operations area boundary. A supplemental HAPs analysis for all potential emission sources and each mine year was analyzed and demonstrated compliance with both the carcinogenic and non-carcinogenic acceptable concentrations. The Johnson Creek Route Alternative does not entail emission source differences of a permanent nature (e.g., roadway construction emissions) that result in long-term criteria pollutant impacts that differ from the 2021 MMP findings, respectively.

**Comparison of Modeled Concentrations to Class I and Class II Increments**

Both near-field and far-field modeling demonstrated that the Class I and Class II air quality increments would not be exceeded outside the Operations Area Boundary. Although evaluation of incremental air
quality impacts is not applicable to minor sources such as the SGP, this provided an indicator of relative SGP impacts under the 2021 MMP.

**HAP Emissions and Hg Deposition**

Emissions of HAPs, including mercury, were quantified for the worst-case LOM Year. Additionally, hydrogen cyanide (HCN), sulfuric acid, Hg, and organic HAPs from fuel combustion, were found to be well below federal major source thresholds. Near-field deposition analysis for Hg indicated that even the maximum predicted deposition rates would be less than significance thresholds.

**Deposition Impacts for Nitrogen and Sulfur compounds at Class I areas and Specified Class II Wilderness Areas**

Predicted deposition impacts, in grams of pollutant per hectare per year, were obtained from far-field modeling for the 2021 MMP peak year emissions. The modeled results were compared to the federal Deposition Analysis Thresholds (DAT) for the three modeled years of 2015 through 2017, the maximum predicted annual deposition rates were below the DAT in each Class I and Class II area evaluated.

**Near-field Plume Blight and Far-Field Regional Haze Impacts**

The Level 2 screening analysis addressed an observer in the nearby Frank Church River of No Return Wilderness (FCRNRW) and demonstrated that the aggregated emissions from the 2021 MMP would have the potential to cause short-term, visible plumes at that wilderness area.

For analysis of regional haze impacts, maximum 24-hour SGP source emissions of SO₂, NOₓ, SO₄, and fine and coarse PM were modeled. The level of regional haze impact in the Class I and Class II areas evaluated was predicted to be minor.

**Climate Change**

The 2021 MMP would create a maximum of 200,671 metric tons of CO₂e annual direct Green House Gas (GHG) emissions. Indirect GHG emission sources associated with this proposal include electrical power generated off-site (but used on-site [97,119 MT]), and emissions from off-site antimony concentrate transport and processing (4,055 MT). Therefore, the total direct and indirect GHG emissions are 301,845 MT. This equates to approximately 0.96 percent of the most recent annual Idaho statewide total GHG emissions (2018). Changes in hydrologic patterns, temperature, and extreme weather events would contribute to a varying level and degree of impacts to resources.

Changes in hydrologic patterns and overall increasing temperatures are expected to result in decreased or degraded soil moisture and quality, air quality, annual streamflow, groundwater recharge, and water quality. Increased surface water temperatures; increased spread of insects and diseases; changes in the timing, duration, and severity of fire seasons; as well as habitat loss and fragmentation also are expected to occur. Closure and reclamation activities under the alternatives could reduce climate change impacts by improving soil quality and implementing best management practices during all phases of the SGP.

Although geotechnical design standards have been developed to help minimize and lessen the extent of potential stability impacts, extreme precipitation events and flash flooding, could lead to more frequent and severe landslides and avalanches. Road maintenance during all SGP phases would improve resilience of the access roads and transportation infrastructure against climate change impacts.
Direct and indirect GHG emissions and their associated impacts would be the same under the Johnson Creek Route Alternative as those discussed under the 2021 MMP.

Baseline conditions would continue and direct and indirect GHG emissions in the vicinity of the SGP area would not change under the No Action Alternative. No additional impacts beyond current trends are expected to occur to the physical, social, and biological resources in the area.

**Soils and Reclamation Cover Materials**

**Total Soil Resource Commitment (TSRC)**

TSRC is the conversion of a productive site to an essentially non-productive site for a period of more than 50 years. Productivity on these areas range from 0 to 40 percent of natural background. Forest Plan Standard SWST03 requires, in an activity area where existing conditions of TSRC are below five percent of the area, management activities to leave the area in a condition of five percent or less TSRC following completion of the activities. The PNF activity area has existing conditions of TSRC at three percent. The BNF activity area has existing conditions of TSRC at one percent. For the PNF activity area the magnitude of impacts to soil resources as a result of the SGP would have a net increase in TSRC that would raise the post-SGP percent TSRC to above five percent under either action alternative (i.e., 17 percent under 2021 MMP, and up to 17 percent under the Johnson Creek Route Alternative).

**Detrimental Disturbance (DD)**

For this analysis (which is comparable among both action alternatives), existing DD within the transmission line ROW is estimated at eight percent. The DD activity area is the area within the transmission line ROW that would be subject to vegetation clearing only and is estimated at up to 500 acres. It is estimated that SGP-related vegetation clearing could initially result in DD as high as 16 percent of the ROW but would more likely be somewhere between 8 and 15 percent. Additionally, the Forest Service would require features designed to minimize DD impacts.

The magnitude of impacts from vegetation clearing potentially include detrimental soil displacement, compaction, and puddling on a conservative estimate of up to 75 acres (15 percent) within the ROW, which would be further reduced by the Forest Service-required mitigation measures that target DD.

**Quantity and Quality/Suitability of Reclamation Cover Materials**

The overall relatively poor quality of the soils at the SGP mine site (outside of valley bottom soils), the long-term stockpiling of growth media (GM) or soil bank material, and the high background concentrations of metals in soils would affect the quality and suitability of available reclamation cover materials. GM used for upland reclamation sites would mostly come from relatively poor upland soils. Overall, the majority of GM used would rate as poor or fair (per suitability criteria), due primarily to texture and coarse fragment content (Tetra Tech 2019). These challenges, coupled with the harsh winter climate (short growing season) and generally steep slopes of the area, would compound the present difficulties in growing and/or maintaining persistent vegetation cover over reclaimed areas. This is consistent with the mixed vegetative cover success of nearby reclaimed mining areas and the previous efforts by Perpetua and others at the mine site to establish self-sustaining cover on previously mined lands that have had some limited success. Additionally, there would be a 797,702 bank cubic yards GM deficit at the mine site according to the balance calculations in the Reclamation Closure Plan. This deficit may be partially met with the surplus of material obtained from the Burntlog Route or could be met through
additional composting of both on- and off-site soil amendments. Thus, there is presently some uncertainty regarding the specific source of material to meet the identified GM deficits under either action alternative. Under the 2021 MMP there would be approximately 278 acres of unreclaimed pits/highwalls. The Johnson Creek Route Alternative would be the same as the 2021 MMP for mine-site related components but would differ due to use of the Johnson Creek Route instead of the Burntlog Route. Because the Johnson Creek Route Alternative does not include GM recovery from the Burntlog Route, it would therefore not have any potential surplus to compensate for the GM deficit at the mine site.

However, Perpetua has committed to salvage the appropriate volume of GM and to create the volume of compost necessary as an amendment to provide suitable quality and quantity of the GM to cover the areas to be reclaimed. Perpetua has also committed to performance criteria tied to slope and soil stability, sediment, and vegetation cover, which would need to be met prior to release of a reclamation performance bond.

The naturally high background levels of trace metals at the mine site represents a challenge with regards to the suitability of GM and reclamation-related revegetation efforts. Perpetua’s proposed 3,000-ppm arsenic limit for suitable root zone material is high. The Forest Service would require limits on the GM for arsenic, mercury, and antimony, and would require a Sampling and Analysis Plan that would include in-situ screening of soils as well as laboratory testing.

Noise

The noise analysis conducted for the SGP examined impacts on 12 defined noise sensitive receivers (NSRs) that were selected based on their approximate location to sensitive areas. Nine of these NSRs had baseline ambient noise levels available, while three did not. Of these 12 NSRs, ten were evaluated for the noise impacts from the SGP, two sites were omitted (Sites 1 and 4). Site 1 represents ambient sound levels near the SGP, and Site 4 is not considered an NSR, but the sound levels measured at Site 4 represent ambient sound levels in adjacent wilderness areas. The ten sites were compared against their baseline ambient noise level, as well as the SGP-set noise threshold of 55 dBA to evaluate the environmental impact to humans, following the Noise Control Act of 1972 and EPAs guidance on ambient noise levels.

Both action alternatives would create some short-term periodic noise exceedance impacts at up to four or five NSRs during SGP, access road, and transmission line construction, depending on the alternative. Construction and/or upgrades of access roads (Burntlog Route and Johnson Creek Route) for either action alternative would impact areas of the FCRNRW – noise would gradually attenuate to not noticeable up to 1.5 miles into the wilderness. Differing impacts to the FCRNRW are due to the distance of the access road to the wilderness boundary – the 2021 MMP utilizing the Burntlog Route is the closest to the FCRNRW for the longest length compared to the Johnson Creek Route Alternative.

Most of the operational activities (i.e., road maintenance and off-site facilities) would produce long-term and periodic noise impacts. Access road traffic and maintenance for both action alternatives would impact some areas of the FCRNRW, with impacts diminishing with distance from the wilderness boundary. Impacts from operations would not extend as far into the wilderness area as they would during construction.
During closure activities, there would be short-term noise impacts from transmission line and access road decommissioning under both alternatives exceeding the baseline ambient noise level, but not the 55 dBA threshold. There would be no irreversible impacts; all noise would cease upon final closure and reclamation.

**Hazardous Materials**

Both action alternatives would include the use, storage, and transport of hazardous materials which, if released, could potentially affect human health and the environment. Hazardous materials to be used would include diesel fuel, gasoline, lubricants, antifreeze, other petroleum products, chemical reagents and reactants (including sodium cyanide and sulfuric acid), antimony concentrate, mercury containing residuals, lime, explosives, and other substances.

Duration of spill risk for both action alternatives would be long term as it would last throughout the life of the SGP. However, the duration of any single hazardous materials spill or release would be temporary (hours or days). A fuel or chemical spill at the SGP facilities would likely be readily contained and cleaned up without any release to the environment.

A spill outside of containment at the SGP site or in transportation would most likely involve liquid fuels or reagents. A small spill of a few gallons, or even tens of gallons, outside of secondary containment would be promptly contained and cleaned up according to the Spill Prevention Control and Countermeasures Plan.

A larger spill of fuel or oil outside of secondary containment would more likely occur in transportation of bulk shipments along public roads or one of the SGP access routes. The proposed controls of transportation of hazardous materials along the SGP access routes, and the availability of SGP spill response resources and trained responders suggest that a spill along the access routes would be promptly contained and cleaned up. However, depending on the amount of material released, the location of the release, weather conditions, and proximity to flowing streams, the impact of the event could be minor to major.

State and federal regulations, project controls, and emergency response procedures would be in place to reduce spill risk and the extent of potential spill impacts.

In general, the potential for a release of hazardous material from a truck accident would be controlled for both the Burntlog and Johnson Creek routes with the use of management practices such as pilot vehicles, speed restrictions, and requiring appropriate spill kits in trucks hauling hazardous materials and in pilot vehicles.

Both the Burntlog and Johnson Creek routes have segments that are exposed to landslides, rockfalls, and avalanches. These geohazards present along the road corridors could increase the potential for truck accidents resulting in spills of hazardous materials. The Burntlog Route has exposure to 26 landslides or rockfalls and 38 avalanche paths. The Johnson Creek Route has exposure to 45 landslides or rockfalls and 94 avalanche paths. The Johnson Creek Route thus may have higher potential for increased trucking accidents and greater spill risk from these geohazards.
Close proximity to surface water resources increases the potential consequences of a significant spill along the access routes. The Burntlog Route crosses 37 streams and includes 9 total miles that are within 0.5 mile of surface water resources. The Johnson Creek Route crosses 43 different streams and includes 27 miles that are within 0.5 mile of surface water resources, including several miles which parallel the fish-bearing East Fork SFSR and Johnson Creek waterways. Though the Burntlog Route includes a greater number of stream crossings, the Johnson Creek Route includes greater proximity to water resources. The potential consequences from significant trucking spills would thus be greater along the Johnson Creek Route.

**Surface Water and Groundwater Quantity**

The SGP would result in stream flow impacts under both action alternatives. Low flow would be reduced at some locations during some periods of the SGP operations up to 14 percent in the East Fork SFSR and up to 40 percent in Meadow Creek.

Dewatering of the pits would lower groundwater levels in the alluvial and bedrock formations during the mining and post closure periods and would reduce flows in local surface water streams that receive groundwater discharge. Additional seep and spring locations fed primarily by groundwater discharge from the dewatered aquifer may also observe flow reductions as an effect of dewatering.

The TSF and TSF Buttress proposed to be located in the Meadow Creek valley would lower groundwater levels and permanently remove six delineated wetland areas within the footprint of the TSF and TSF Buttress. The permanent reduction in local groundwater levels would be due to the installation of liner and cover systems over these facilities to inhibit meteoric recharge leaching through the mined materials. The cover systems placed over the Yellow Pine pit backfill and the Hangar Flats pit backfill would have a similar effect on groundwater levels at those locations.

**Surface Water and Groundwater Quality**

All action alternatives would include handling and storage of mineralized materials which could potentially leach major ions, total dissolved solids (TDS), and/or metals and could result in adverse impacts to surface water and/or groundwater chemistry. Mineralized materials that would be managed include ore, development rock, and newly generated tailings. Similarly, mineralized materials would be exposed in pit walls, also resulting in exposure to oxygen and water, and the potential for leaching. Several proposed activities, including storage of mineralized materials above engineered liners and/or below engineered covers, diversion of stormwater and surface water around the disposal locations, and movement of legacy mineralized materials (tailings) from their current locations to engineered disposal facilities, would reduce, but not eliminate, the potential for the release of leached chemicals to surface water and groundwater.

The analysis shows that remaining rock in pit walls and the development rock, deposited in the TSF Buttress and pit backfills, would be largely non-acid generating, but would be capable of leaching aluminum, antimony, arsenic, cadmium, copper, manganese, mercury, zinc, sulfate and TDS into surface water and groundwater in concentrations that exceed water quality criteria. Therefore, active contact water collection and water treatment would be required for a period of time during the operations and post-closure period until geochemical stability of mined materials could be achieved. In the case of the
TSF where stabilization would depend on consolidation of tailings plus liner and cover installations over the tailings, this collection period would be approximately 40 years. The water treatment would prevent mine-impacted waters with elevated analyte concentrations from contacting surface water in the environment. Upon closure, inundation of development rock placed in pit backfills would result in analyte leaching from the backfilled material to alluvial and bedrock groundwater. However, this leaching would not materially affect the utilization of groundwater compared to its existing condition where it frequently does not meet water quality criteria except for an area where antimony and arsenic concentrations are below groundwater standards.

Surface waters also would be impacted by modification of temperature due to removal of shading vegetation, development of pit lakes, and modification of stream depth during construction, operations, or the post closure/reclamation period. Compared to existing conditions, project operations are predicted to increase temperatures in West End Creek and the East Fork SFSR below the Yellow Pine pit area. Upon closure activities, Meadow Creek temperatures are predicted to increase as the stream channel is restored atop the TSF while formation of the West End pit lake raises temperatures in West End Creek. With the exception of the West End Creek segment below the pit area, predicted temperatures return to existing conditions over a period of approximately 100 years.

Surface water quality also could be impacted by increased sedimentation associated with mining activities, access road construction and use, and the construction and maintenance of required utilities, with the greatest potential for in-stream impacts occurring during times of higher overland flow. The effect to surface water quality as a result of sedimentation and erosion would be limited by environmental protection measures and control techniques, by the limited duration of active surface disturbing activities, and by the adaptability of the receiving environment.

However, under existing conditions, streams in the SGP area (except for West End Creek) are listed as impaired for specific uses in accordance with Clean Water Act Section 303(d). The causes for listing of these waters are associated with arsenic (plus antimony and mercury at some locations) for exceedances of Idaho's human health criterion for consumption of water and organisms. Operational and post-closure concentrations of these elements in the East Fork SFSR are predicted to be comparable to or less than the existing conditions.

Groundwater analyte concentrations beneath the mine site, particularly in the vicinity of the TSF, TSF Buttress, Hangar Flats pit backfill, and Yellow Pine pit backfill, are expected to increase in response to constituent leaching from development rock. However, existing groundwater in those areas typically does not meet regulatory criteria for use as drinking water due primarily to arsenic and antimony concentrations.

There are no active domestic groundwater wells used for residential drinking water within 15 miles of the SGP. Because groundwater is not currently used as a public drinking water source at the SGP and is assumed to be unlikely to be used as a drinking water source in the future, the Agency for Toxic Substances and Disease Registry Public Health Assessment conducted for the existing mine site eliminated the groundwater as drinking water pathway from consideration as a public health concern (ATSDR 2003). With regard to wetland and riparian areas, changes to water quality parameters would occur under the 2021 MMP during the construction and operation phases. The 2021 MMP would improve...
some of the existing water quality conditions observed in Meadow Creek and the East Fork SFSR by removing and repurposing legacy mine wastes. However, the 2021 MMP would have direct permanent impacts on water quality, as it would contribute new sources of mine waste material to the East Fork SFSR drainage.

Despite analysis area improvements to water quality as a result of the removal and reclamation of legacy mine wastes, exceedances of the most stringent water quality standards (including both human health and aquatic life) for water column antimony, arsenic, copper, and mercury are anticipated. In considering only the aquatic life criteria, which are more relevant for the protection of fish species, impacts due to antimony and arsenic are not anticipated. For copper and mercury, impacts may be minimal but uncertainties in predicting future conditions exist.

**Vegetation**

Overall, the 2021 MMP-related vegetation clearing would impact 3,564 acres, including primarily undisturbed areas for the Burntlog Route where an increase in the potential for non-native plant establishment and spread would be more deleterious. The Johnson Creek Route Alternative would impact 3,399 acres through vegetation clearing; however, much of the disturbance area would be along or near previously disturbed areas (i.e., existing roads) where non-native plants are already established or could become established as a result of previously authorized activities.

The 2021 MMP would remove an estimated 259 acres of occupied whitebark pine habitat (12.5% of occupied habitat in the analysis area), totaling 1,236 trees (23 would be mature, cone-bearing). Impacts to the whitebark pine would be less under the Johnson Creek Route Alternative as an estimated 108 acres of occupied whitebark pine habitat (5.2% of occupied habitat in the analysis area), totaling an estimated 767 trees (23 would be mature, cone-bearing trees) would be removed.

The 2021 MMP would impact known occurrences of bent-flowered milkvetch, least moonwort, Sacajawea’s bitterroot, Blandow’s helodium, sweetgrass, and Rannoch-rush, while the Johnson Creek Route Alternative would impact known occurrences of bent-flowered milkvetch, least moonwort, and Sacajawea’s bitterroot. Additionally, the 2021 MMP would impact a greater amount of modeled potential habitat (3,991 acres) for sensitive and forest watch plant species than the Johnson Creek Route Alternative (3,204 acres).

Impacts as a result of increased potential for non-native plant establishment and spread may be regional in nature due to the relatively large amount of habitat disturbance associated with the 2021 MMP and Johnson Creek Route Alternative.

**Wetland and Riparian Areas**

**Loss of Wetland and Riparian Areas**

**Mine Site Focus Area**

The 2021 MMP and the Johnson Creek Route Alternative would result in the same loss of 120 wetland acres within the mine site focus area (approximately 28 percent of the 429 total acres of wetlands within the SGP analysis area) and 619 acres of riparian areas.
**Off-Site Focus Area**

Wetlands and riparian areas in the off-site focus area would be impacted by the action alternatives. The off-site area includes features such as Big Creek - North Fork Payette River, Cascade Reservoir, Gold Fork River, Johnson Creek, Lake Fork - North Fork Payette River, Headwaters East Fork SFSR, and Upper South Fork Salmon River.

Losses of wetlands due to the 2021 MMP in this area would be 76.3 acres and the Johnson Creek Alternative would result in the loss of 71.2 acres. Perennial stream lengths affected would be 4.44 miles for the 2021 MMP and 4.14 miles for the Johnson Creek Alternative and lengths of non-perennial streams impacts would be 2.78 miles and 2.23 miles, respectively. Riparian area losses would be 300 acres for the 2021 MMP and 353 acres for the Johnson Creek Route Alternative. Differences of impacts to wetland and riparian acreages outside the mine site focus area are predominantly due to the absence of the Burntlog Route disturbance under the Johnson Creek Route Alternative.

**Impacts on Wetland and Riparian Functions**

The losses of wetland functional units by action alternative would be 1,054 for the 2021 MMP and 1,028 for the Johnson Creek Route Alternative with 376 and 371, respectively of these functional units attributed to Category II wetlands (high value) and the rest Category III and IV.

**Alteration of Wetland and Riparian Areas due to changes in Water Balance**

Impacts due to groundwater drawdown would be the same for both alternatives since construction, operation, and reclamation activities would be the same within the mine site focus area. The action alternatives may vary in indirect effects due to roads, but those indirect effects have not been quantified. However, given the small amount of wetlands affected in the off-site focus area relative to the mine site focus area, the differences between the two action alternatives would be minimal.

**Alteration of Wetland and Riparian Areas due to Changes in Water Quality**

Both action alternatives would have direct permanent impacts on water quality due to contributions of new sources of mine waste material to the East Fork SFSR drainage. Indirect effects to wetlands and riparian areas could occur if the quantity and or quality of surface and groundwater flows, including the chemical characteristics of the waters, change downstream of disturbance areas. Removal and repurposing of legacy mine wastes would occur under both action alternatives, thereby improving some existing water quality conditions observed in Meadow Creek and the East Fork SFSR.

Under the Johnson Creek Route Alternative, water quality effects on wetlands and riparian areas would be similar as described under the 2021 MMP, although the absence of construction or use of the Burntlog Route would eliminate water quality impacts in this area as compared to the 2021 MMP. As the Johnson Creek Route is parallel and near Johnson Creek and the East Fork SFSR along much of its route, these effects would be concentrated in these streams, whereas the Burntlog Route would cross several drainages resulting in less impact on any one drainage.

**Compensatory Mitigation for Losses of Aquatic Resources**

In order for the USACE to issue a permit under Section 404 of the CWA and authorize dredge or fill placement in WOTUS, all unavoidable impacts to jurisdictional WOTUS must be mitigated. The final rule for Compensatory Mitigation for Losses of Aquatic Resources (U.S. Environmental Protection Agency and USACE 2008) states a preference for achieving mitigation by first trying to find available.
wetland mitigation credits from an agency-approved wetland mitigation bank. When mitigation bank credits are not available, the final rule directs 404 permit applicants to seek out opportunities to use in-lieu fee programs to satisfy mitigation needs. In-lieu fee programs are generally operated by public resource agencies that accept money for wetland impacts within a specific geography and periodically use that money to fund wetland restoration, creation, or enhancement projects within that same geography. Perpetua proposes to accomplish compensatory mitigation for impacts to wetlands through a combination of mitigation bank credits in the North Fork Payette subbasin and permittee-responsible on-site mitigation within the SFSR subbasin (Tetra Tech 2021b).

**Fish Resources and Fish Habitat**

For fish and aquatic habitat, the important factors involve the removal and placement of barriers such as the Yellow Pine pit and TSF/TSF Buttress (which affect species differently), the modifications in surface water management and flows at the mine site, fish access through the East Fork SFSR tunnel, and stream channel restoration effects on stream temperature. The principal difference between alternatives is associated with the risk of transportation-related spills along access routes. Under the 2021 MMP, during construction, 6.5 miles of the transportation route would be within 100 feet of streams but would be reduced to 1.69 miles of route within 100 feet of streams once the Burntlog Route was constructed. The Johnson Creek Route Alternative would have 6.5 miles of transportation route within 100 feet of streams for the duration of the SGP.

Reclamation and stream restoration activities post-closure generally improve habitat conditions compared to the operational period as flows and channels are re-established. However, stream temperatures are increased in restored stream channels until revegetation establishes to provide riparian shading for the streams.

Individual fish would be affected by dewatering, salvage, and relocation due to modification of stream channels and dewatering of the existing Yellow Pine pit lake. Fish salvage would be required for dewatering and all in-water work at stream crossings in all fish-bearing water bodies. Management of individuals affected would be conducted under the Fisheries and Aquatic Resources Mitigation Plan and Fishway Operations Management Plan.

Alterations to mine area surface streams including the elimination of the Yellow Pine pit lake, construction of the East Fork SFSR fish tunnel, and removal of existing barriers would alter fish occupancy and available habitat during construction and operations primarily by allowing fish access to portions of the East Fork SFSR and relocating the barrier on Meadow Creek upstream.

During operations summer maximum stream water temperatures in Meadow Creek and the East Fork South Fork would decrease due to diversion of Meadow Creek around the TSF and TSF Buttress. Upon closure and routing of Meadow Creek to the restored stream channel on top of the reclaimed TSF, summer maximum stream temperatures would increase due to the time needed for revegetation to result in riparian shading of the stream. Over time, summer maximum stream temperatures would decline to near or below baseline conditions.

Changes in water chemistry due to mining activities would not negatively affect fish because predicted concentrations for key constituents are comparable or lower than existing conditions. Effects of spills,
sedimentation, and turbidity on water quality would be managed through Forest Service requirements and project design features to minimize these effects.

Stream flow reductions would affect fish productivity during operations, but productivity would return toward existing conditions as stream flows recover over time. Post-closure stream flows and productivity would decrease in Meadow Creek and the East Fork SFSR upstream from Meadow Creek by 1 percent and 2 percent, respectively due to hydrological and physical changes associated with the project. Flows and productivity in the East Fork SFSR downstream from Meadow Creek would return to existing conditions post-closure.

The combination of physical stream channel changes, direct effects to individuals, and changes to many of the WCIs (e.g., temperature, stream flow) would affect Chinook salmon and habitat in the analysis area. SGP activities that would potentially cause these impacts include, but are not limited to, new road construction, transportation including hazardous materials, stream diversions, and construction and operation activities at the mine site. These effects may cause injury or mortality to individuals and temporarily or permanently displace Chinook salmon from several mine site streams during certain periods when habitat conditions become unsuitable. This would cause a temporal loss of habitat. Following closure and reclamation, the overall net effect from the SGP would be a net increase in available habitat; however, flows and temperatures make the additional habitat less optimal.

There would be similar operational period effects on steelhead trout, bull trout, and westslope cutthroat trout. Effects for trout species differ from Chinook salmon following closure and reclamation, as there would be a net increase in both the quantity and quality of habitat for steelhead trout and net decreases in both quantity and quality of habitat for bullhead trout and westslope cutthroat trout.

**Wildlife**

The 2021 MMP and Johnson Creek Route Alternative would remove an estimated 3,266 acres and 3,096 acres, respectively, of wildlife habitat, including habitat for Canada lynx (194 and 175 acres, respectively), wolverine (2,342 and 2,005 acres, respectively), northern Idaho ground squirrel (63 acres), Monarch butterfly, Region 4 sensitive species and management indicator species, Idaho species of greatest conservation concern, general wildlife species, big game species, and migratory bird species and bald and golden eagles.

Direct impacts to wildlife species may include direct mortality (i.e., wildlife-vehicle collisions, removal of nest or roost trees, etc.) or loss of habitat due to land clearing activities and land use changes. Indirect impacts could include reduced use of foraging or breeding habitat or reduced prey resources in the analysis area.

Within the Operations Area Boundary, direct effects on wildlife species would primarily be due to loss and fragmentation of habitat; direct mortality through vehicle-wildlife collisions; and disturbance from light, noise, fugitive dust, and increased human activity under the 2021 MMP and Johnson Creek Route Alternative. Wildlife would likely be displaced around the perimeter of the mine site. Additional roadways in the Operations Area Boundary would expose individuals to direct vehicle collisions or increased hunting pressure from humans in the wildlife analysis area. Light, noise, and fugitive dust impacts associated with mine site activities are likely to disturb or displace wildlife species. However,
because the existing (ambient) sound levels vary between 20 and 40 dBA, it is likely that SGP area wildlife would have a higher tolerance for noise. Equipment would have limited external lighting and would employ noise-minimizing practices. As part of the SGP, buildings, equipment, and drill rigs would have limited external lighting when feasible. The result would generally be a reduction in the area of habitat disturbed at most sites.

As a result of new access roads, limited to the 2021 MMP and not the Johnson Creek Route Alternative, direct effects on wildlife species would primarily be due to loss and fragmentation of habitat; direct mortality through vehicle-wildlife collisions; and disturbance from light, noise, fugitive dust, and increased human activity. Construction of 15 miles of new road for the Burntlog Route would likely fragment habitat for general wildlife species and may act as a barrier to movement for some species. The intensity of this impact could range from minor displacement to mortality. The duration ranges from temporary road construction to short-term. It is not expected that the increased risk of injury or mortality would become permanent, because the new segment of the Burntlog Route would be reclaimed, and traffic levels on the existing roads would return to current levels.

Regarding utilities, direct impacts on wildlife species may include loss or fragmentation of habitat along utility corridors, substations, and communication towers due to land clearing activities and land use changes under the 2021 MMP and Johnson Creek Route Alternative. The addition of new utility access roads, as well as new transmission lines, and upgraded transmission lines, could impact individual wildlife species. Construction impacts would likely displace wildlife but would be temporary. Vegetation would be cleared only in those areas necessary for 2021 MMP and Johnson Creek Route Alternative activities to preserve natural habitat to the greatest extent practicable. However, impacts to forested wetlands would likely be permanent as ROW management practices generally do not allow the establishment of woody vegetation.

Construction and operation of the off-site facilities under the 2021 MMP and Johnson Creek Route Alternative are unlikely to disturb most wildlife species, because construction activities are not planned to occur in suitable habitat used by them. Although construction and operation of the off-site facilities themselves would likely not cause direct mortality to wildlife species, vehicle traffic associated with the facilities could result in mortality.

The important differences among the alternatives lie in the acres of habitat loss, the amount and location of the disturbance from noise and human activity, new access roads, and the location of the facilities. The Johnson Creek Route Alternative would have 170 fewer acres than the 2021 MMP due to the elimination of the Burntlog Route which also would reduce the magnitude and extent of impacts on most wildlife, especially wolverine, big game, and migratory birds. However, under both alternatives, greater impacts would occur for several groups of wildlife (e.g., big game [moderate impacts] and wolverine [major impacts]) due the species known occurrences and location and amount of habitat disturbance associated with the SGP.
Timber Resources

The 2021 MMP would result in vegetation clearing on 595 acres containing 438,243 cubic feet of sawtimber and sub-merchantable product, while the Johnson Creek Route Alternative would result in vegetation clearing on 733 acres containing 547,984 cubic feet of sawtimber and sub-merchantable product. Permanent impacts under the 2021 MMP would occur on 66 acres containing 12 acres of land suited for timber production in Management Prescription Categories (MPCs) 5.1 and 4.2, with approximately 206 million board feet (MBF) of sawtimber. The Johnson Creek Route Alternative would result in permanent impacts to 282 acres in the analysis area that contain 28 acres of land suited for timber production in MPCs 5.1 and 4.2, with approximately 808 MBF.

To address the loss of timber resources within the timber resources analysis area, 111 acres would be replanted during reclamation with conifer and other tree species under the 2021 MMP and Johnson Creek Route Alternative. Areas identified for timber species replanting are entirely within the mine site, where lands would either be treated to regenerate forest conditions (planted at 81 trees per acre) or park-like conditions (planted at 170 trees per acre) under two conditions: cool aspect and general aspect. Planted timber species would include primarily Douglas-fir and lodgepole pine, with the inclusion of Engelman spruce on the cool-aspect sites.

Land Use and Land Management

The SGP would primarily occupy National Forest System (NFS)-managed lands, with the majority of impacts on PNF lands. Land use would be impacted by expansion of the mine site and associated mining activities and facilities (access roads, utilities, and off-site facilities). Other land uses (agriculture, fisheries, timber harvests, tribal, and recreational and special uses) would be impacted by the conversion of land to mine uses. These impacts are described in other resource sections within this SDEIS. Table ES-2 shows the total acreage impacts from each mine component that would result from each action alternative.

Either action alternative would require new mine or related infrastructure to be built on previously undisturbed private, state, NFS, and Bureau of Reclamation lands. Table ES-3 shows the acreage of impacts from the mine components by action alternative.

The action alternatives would require new ROWs or easements to accommodate the construction of new and upgraded access roads and transmission lines. These impacts would be located on private, state, and NFS lands; new transmission line ROW would not cross any Bureau of Reclamation lands for either action alternative. New ROWs on NFS lands are considered a direct effect to land use and may be authorized under Forest Service special uses regulations at 36 CFR 251 or under 36 CFR 228A depending on the type of use, location, and other factors. For purposes of this environmental analysis, the agency is assuming the proposed uses would be able to be authorized under existing regulatory authorities. However, the agency will need to evaluate the eventual applications for rights of way to make a final determination. ROW authorizations on private lands in Valley County would require a conditional use permit, and ROW authorizations on lands owned by the State of Idaho would require coordination with IDL. Table ES-4 provides the acreage of new ROW required for each alternative.

Access and Transportation

Traffic Volumes

During construction, mine traffic under the 2021 MMP and Johnson Creek Route Alternative would generate an estimated annual average daily traffic (AADT) of 65 vehicles (45 heavy vehicles and 20 light vehicles). Construction traffic volumes on Johnson Creek Road and Stibnite Road would almost double and triple, respectively. Over a third of the vehicles traveling on these one-lane, native surfaced roads would be comprised of heavy vehicles and could result in slower travel times for non-mine-related traffic and may deter other travelers from using these roadways. Travelers may use alternative roadways including McCall-Stibnite Road to South Fork Salmon River Road.
During operations, mine-related traffic would include transport of employees to and from the SGP, delivery of supplies, and activities associated with road maintenance such as snowplowing and sanding. Under the 2021 MMP and the Johnson Creek Route Alternative, operational AADT would be 50 vehicles (33 heavy vehicles and 17 light vehicles), resulting in approximately four mine-related vehicles per hour traveling outside the SGP.

The upgraded Burnt Log Road and the newly constructed Burntlog Route would experience an increase in traffic of over 71 percent under the 2021 MMP, with 27.5 percent of the traffic comprised of heavy vehicles. Although heavy vehicles currently use Johnson Creek Route to access the SGP, the Johnson Creek Route Alternative traffic would result in a noticeable change in baseline driver experience and slower drive times due to the substantial increase in mine-related heavy vehicles along the Johnson Creek Route during the life of the SGP. Even though upgrades to Johnson Creek Road and Stibnite Road would be made, these roads would still have many curves and slopes.

During closure and reclamation, activities including slope recontouring, facility removal, seeding and planting, and post-closure environmental monitoring would require approximately 7 years. Closure and reclamation would generate a total estimated AADT of 27 vehicles (15 heavy vehicles and 12 light vehicles). Post-closure monitoring activities would generate a total estimated AADT of six light vehicles.

Local roads experience a seasonal effect which results in noticeable differences in traffic. Valley County has many summer recreational areas that attract visitors from May through October with peak AADT levels in June, July, and August. Mine access via the Johnson Creek Route would be more impactful on summer recreational traffic because it would utilize established roads rather than new road development. Winter driving conditions influence the amount of traffic and result in lower AADT levels during the winter months. Therefore, the effect of SGP traffic on these roads would show a noticeably greater increase in mine-related winter traffic during winter. Post-closure winter traffic would not be as noticeable as heavy vehicle deliveries would not occur and approximately six mine-related light vehicles per day would utilize the accessible roadways in the analysis area for monitoring and maintenance purposes.

Public Access
Under the 2021 MMP, public access to the SGP area would be enhanced by the development of a new access road (Burntlog Route) compliant with current road standards. Under both action alternatives, there would also be a controlled public access route through the SGP during the operations, and closure and reclamation phases; however, public access would be intermittently interrupted during the construction phase. Under the Johnson Creek Route Alternative, the Burntlog Route would not be constructed, and the Johnson Creek Route would be used for both public and SGP-related access. To continue providing OSV access to Landmark, a 10.4-mile groomed OSV route between Warm Lake and Trout Creek Campground on Cabin Creek Road would be created as part of the 2021 MMP along with a parking area, resulting in a new winter access facility that would be maintained by Valley County.

Safety and Emergency Access
For the duration of the SGP, the increase in total volume of mine-related vehicles, specifically heavy vehicles or trucks, on the Yellow Pine and Burntlog routes would result in an increased risk for accidents occurring between public and SGP-related traffic due to the one-lane constraints during construction, for
passing slower moving vehicles, and degradation of the road with more frequent heavy vehicle travel. Proposed controls for deliveries of hazardous materials would address the risk of accidents for those convoys. The steep terrain would be a greater risk to safety along the Johnson Creek Route under the Johnson Creek Route Alternative as it would be the only route used for the life of the SGP and would require safety considerations for geotechnical hazards, landslides, and avalanche zones, including intermittent and extended road closures during the four years of construction. Additionally, access into the SGP mine site under the Johnson Creek Route Alternative would be through a single point of ingress and egress and would require additional safety considerations for mine deliveries and public access. The steep climb to provide access around the Yellow Pine pit would require a wider road with more switchbacks to accommodate the heavy trucks transporting mine supplies and may increase hazardous driving conditions for crew rotation, emergency responses, and wildfire evacuation.

**Other Modes of Transportation**

Under both action alternatives, a helipad would be located at the SGP for exploration during daylight hours, Medevac purposes, and avalanche control activities. Approximately one round trip (two truck trips) of antimony concentrate would be hauled off-site daily. The daily shipment of antimony and the potential transport of supplies and materials to and from the SGP would generate minimal to negligible changes in regional water transportation. Although there is no commercial rail transportation system in the analysis area, there is potential for the trucks to transport mine products to rail lines located in Boise or for supplies and materials to be indirectly transported to and from the SGP by trucks originating from rail shipments. Nevertheless, these impacts would generate negligible changes to rail transport during operation of the SGP and would not substantially alter the regional level of service.

**Heritage Resources**

There are 143 potential historic properties (NRHP-eligible or unevaluated heritage resources) within the areas of potential effects (APEs). Adverse effects have been identified for up to six historic properties, depending on the action alternative. Adverse effects to additional historic properties could occur, although historic properties within the transmission line footprint and access road construction footprint could potentially be avoided.

There is an undisclosed number of potential Traditional Cultural Properties (TCPs) and Cultural Landscapes (CLs). The Forest Service is in ongoing consultation with the Nez Perce Tribe, Shoshone-Bannock Tribes, and the Shoshone-Paiute Tribes to determine what protected information can be made public.

One historic property is located at the SGP (Site 10VY1488, the Stibnite Lithic site). This archaeological site would be adversely impacted under either action alternative due to construction impacts associated with the transmission line. Impacts could be minimized or avoided through redesign in this area.

Two historic properties (Old Thunder Mountain Road [FR 440] and IPCo Line 328) are linear sites that pass through and beyond the analysis area. No adverse effect would occur to the IPCo Line 328 under the 2021 MMP or the Johnson Creek Route Alternative. Under the 2021 MMP, the Burntlog Route would overlap about 2 miles of the 25-mile long Old Thunder Mountain Road. Old Thunder Mountain Road is currently part of FR 440 (an all-terrain vehicle road) and would not be realigned by the SGP. Therefore, no adverse effect would occur.
Three of the six historic properties are Forest Service administrative buildings (Landmark Ranger Station, Meadow Creek Lookout, and Thunderbolt Lookout). Under the Johnson Creek Route Alternative, the Johnson Creek Road would be upgraded in the area of the Landmark Ranger Station and used for mine access for the life of the SGP; although physical disturbance to the historic property would be avoided, there could be visual, noise, and vibratory impacts to its integrity from the Landmark Maintenance Facility constructed within its viewshed and increased noise and vibration due to increased traffic including heavy vehicles on the Johnson Creek Road. Effects to the Landmark Ranger Station would be minimal under the 2021 MMP because the road would not be improved and would only be utilized during construction of the SGP. At the Meadow Creek Lookout, a new VHF repeater site would be constructed. Addition of this equipment to the setting would cause an adverse effect under the 2021 MMP, as this would only be needed for the Burntlog Route. The Thunderbolt Mountain Lookout, a potential historic property that has not been formally inventoried, would be subject to similar impacts.

The introduction of visual elements would alter the integrity of setting, feeling, and/or association of certain historic properties. Under both action alternatives, the Stibnite Lithic Site and the Meadow Creek Lookout would be subject to altered viewsheds. The Johnson Creek Route Alternative’s Landmark Maintenance Facility would alter the Landmark Ranger Station’s viewshed. Under either action alternative, effects from increased visual intrusions also are of concern for TCPs or CLs that could be present in the APE.

The potential impact for noise is the same for either action alternative. Noise levels higher than ambient also could affect use of TCPs or CLs by creating a distraction and altering the sense of solitude and feeling of the natural environment.

Ground disturbance totals vary between the action alternatives. The 2021 MMP would disturb 3,266 acres, while the Johnson Creek Route Alternative would disturb 3,095 acres. In general, reduced ground disturbance lowers the potential for impacts and for inadvertent cultural resources discoveries during construction.

In summary, potential impacts to historic properties caused by ground disturbance, the introduction of new visual elements, and/or noise and vibration disturbances do not vary substantially between the action alternatives. Physical impacts would affect, at a minimum, between five (2021 MMP) and six (Johnson Creek Route Alternative) historic properties that include the Landmark Ranger Station, Meadow Creek Lookout, Thunderbolt Lookout, IPCo Line 328, a historic road/Native American travel corridor (Old Thunder Mountain Road), and the Stibnite Lithic site. Visual impacts could adversely affect four to five historic properties that include the lookouts, the ranger station, and the Stibnite Lithic site.

If avoidance of other historic properties along other SGP components such as the transmission line and off-site facilities cannot be avoided by construction, then additional impacts would occur. Under the 2021 MMP, 46 historic properties would be within the physical APE and an additional 97 historic properties within the visual, auditory, and vibratory (VAV) APE. Of those there is potential for 19 to have physical impacts, 68 could experience visual effects, 15 that may be susceptible to vibratory effects, and 16 whose integrity could be affected by noise.
Under the Johnson Creek Alternative, 44 historic properties would be within the physical APE and an additional 86 historic properties within the VAV APE. Of those there is potential for 18 to have physical impacts, 66 could experience visual effects, 14 that may be susceptible to vibratory effects, and 15 whose integrity could be affected by noise.

All of these types of impacts, as well as access restrictions caused by the SGP for a period of 20 years, could affect integrity of TCPs and CLs and the ability of tribes to access these resources under both action alternatives.

The potential indirect effects from possible future increased access to the analysis area due to additional and upgraded roads is generally the same under either action alternative. Traffic may increase over current use, and this could possibly create an indirect effect to heritage resources by making them more visible and more vulnerable to damage or vandalism.

Any areas within the physical APE proposed for disturbance that have not been surveyed would be inventoried prior to SGP-related ground disturbing activities that may impact historic properties in accordance with stipulations in the Programmatic Agreement. The agreement also would include provisions for identifying TCPs and CLs prior to ground disturbance associated with the SGP. Additionally, it would identify mitigation measures for historic properties and how the Forest Service would ensure that they are carried out.

**Public Health and Safety**

Potential public health and safety impacts (both positive and negative) were evaluated. These effects would be primarily related to alterations of environmental conditions, economic conditions, local public services, and infrastructure. Removal of legacy mine materials along with regulatory requirements and project design features minimizes effects associated with air quality, soil quality and water quality resulting from changing environmental conditions.

Associated with changes in economic conditions, there would be greater exposure to natural hazards such as avalanches due to the increase in the number of people traveling and working in the area. Further, economic dislocation and disruption to the local area economy after cessation of mine operations (“boom and bust” impacts) may occur but may be somewhat offset by the residual positive impacts of SGP operations on socioeconomic conditions.

Public services and infrastructure would be affected by increased use during construction and operations but would benefit from improvements to roads and access plus upgrades to electrical power utilities. Emergency medical technicians and emergency equipment and supplies would be on-site, including an ambulance, first aid, and medical supplies. These facilities would minimize the demand on the local services and provide medical services for workers and site-visitors in an otherwise remote area. However, with 500 or more employees living and dining in relatively close quarters, the potential for transmission of infectious diseases exists. Employees from the local community who lodge at the on-site facility could potentially transmit infectious diseases to the local communities upon return from the on-site housing facility. Therefore, worker safety protocols include basic measures for good hygiene and protection of infectious disease transmission; and on-site health care services would provide basic treatments for worker illnesses.
Recreation

Both action alternatives would result in impacts to recreation access, settings, opportunities, use, facilities, and recreation-related special use permits. The SGP would remove the mine area from recreation use and alter the recreation setting in the surrounding area due to visual changes and noise. Use of Warm Lake Road (CR 10-579) and the Johnson Creek Route during construction would affect access and the recreation setting for facilities along Johnson Creek and Warm Lake Roads. Winter plowing of Johnson Creek Road (CR 10-413) during construction would affect access to other OSV routes. New winter motorized access would be provided on the Cabin Creek Road OSV route. Construction of many SGP facilities may have temporary impacts to recreation (access, opportunities, use) and may alter the recreation setting of the areas within and adjacent to these facilities. The SGP also would affect access to operating areas of three outfitters and guides, affect their ability to provide activities, and may degrade customer’s recreation experiences.

Under both action alternatives, temporary closure of the connection between the Stibnite and Thunder Mountain roads through the SGP would affect access and use of sites off these roads until the connecting route through the SGP was constructed. Road access through the SGP would provide controlled access to the Thunder Mountain Road area for the public and permitted outfitters.

The Burntlog Route under the 2021 MMP would offer new motorized access where such access does not currently exist and could increase recreation use in areas surrounding these facilities. These facilities also may displace wildlife-based and non-motorized recreation opportunities and would alter the recreation setting for the FCRNRW and two dispersed camping areas. Due to its closeness to the FCRNRW border, a portion of the Burntlog Route would result in additional change to the recreation setting for wilderness activities, potentially induce increased use of the Black Lake area and FCRNRW, and potentially result in unauthorized motorized use of the FCRNRW. The Burntlog Route may have an increased impact on the ability of the two permitted outfitters to provide permitted activities due to the impacts on wilderness activities. The maintenance facility under the 2021 MMP would be located along the Burntlog Route, but construction noise may affect the Mud Lake dispersed camping area, which also would be affected by construction of the Burntlog Route.

The Burntlog Route would not be developed under the Johnson Creek Route Alternative. Therefore, there would be no adverse or beneficial impacts to recreation from this route compared to the 2021 MMP. Instead, the Johnson Creek Route would be used during all phases of the SGP. Construction impacts of using the Johnson Creek Route under the Johnson Creek Route Alternative would be similar to the 2021 MMP, except periodic temporary closures on Johnson Creek Road and daily closures on Stibnite Road would result in reduced access and recreation opportunities and impacts to visitor experiences along Johnson Creek, Stibnite, and Thunder Mountain Roads and locations accessed from these roads, potentially including the Big Creek area depending on where the closure would be located along Stibnite Road. Construction would also take two years longer for the Johnson Creek Route Alternative.

Unlike the 2021 MMP, impacts from use of the Johnson Creek Route under the Johnson Creek Route Alternative would continue through operations and closure/reclamation instead of ending once the Burntlog Route was completed (except for impacts from road closures as these would not occur during operations or closure/reclamation). The maintenance facility would be located at Landmark, increasing recreation impacts in that area. Under the 2021 MMP, impacts to recreation in the winter from the...
Johnson Creek Route would be similar to the 2021 MMP, except plowing of Johnson Creek Road and grooming of the OSV route along Johnson Creek Road would continue through closure and reclamation. In addition, under the Johnson Creek Route Alternative, the Johnson Creek OSV route would be longer (up to Wapiti Meadow Ranch). After reclamation under the Johnson Creek Route Alternative, Stibnite Road improvements would remain and could increase access for more vehicles and affect the recreation setting.

**Scenic Resources**

**Change in Landscape Character and Scenic Quality of the Analysis Area**

The action alternatives would cause similar changes to local landscape scenic qualities over the construction, operation, and closure and reclamation timeframes. The No Action Alternative would result in no change to landscape character and scenic quality. The 2021 MMP would result in the greatest change in landscape character and scenic quality, primarily due to construction and operation of the Burntlog Route in addition to the SGP mine site. The Johnson Creek Route Alternative would entail less change to landscape character and scenic quality of the analysis, as the mine access route would not require construction of the Burntlog Route. After operations, new portions of the Burntlog Route would be decommissioned, and visual impacts would lessen over time.

**Change in Distance Zone**

The 2021 MMP would result in the greatest change to distance zones, because it would require construction of a new roadway in the forest. Individuals traveling through the forest on the new roadway would be able to see areas of the forest either not seen from viewing platforms under existing conditions or see them from a closer distance. The 2021 MMP would add the largest amount of new access roads. Under the 2021 MMP, the SGP would be in the middleground distance zone of the new roadway for approximately 2 miles. Both alternatives would involve construction of the new Thunder Mountain Road link that would traverse through the SGP providing immediate foreground views of the SGP.

**Change in Nighttime Lighting**

Nighttime lighting at the SGP would be the same for both action alternatives. Similarly, there would be nighttime lighting effects from vehicles traveling on roads (new or improved) under both action alternatives. The 2021 MMP would include the greatest mileage of new roadway, but some of these would occur at higher elevations, potentially increasing distant visibility. The Johnson Creek Route Alternative would not include construction of Burntlog Route, but nighttime lighting effects would increase along the Johnson Creek Route, which potentially has more viewers to experience them as there are residences in the village of Yellow Pine and ranches along Johnson Creek Road (CR 10-413).

**Context of Impacts per Forest Guideline Visual Quality Objectives**

Under both action alternatives, the SGP, access routes, new and upgraded transmission lines, and off-site facilities would introduce moderate to major levels of visual contrast to areas with local and regional scenic importance as indicated by Preservation, Retention, and Partial Retention Visual Quality Objectives (VQOs) and in certain areas would be in conflict with established Forest Service VQOs.

**Changes to Scenic Integrity**

The analysis area generally has moderate scenic integrity because the landscape is altered by existing roads and transmission lines. Scenic integrity is low where existing disturbances are present from
historical mining activities. Under both action alternatives, additional alterations would occur to the already impacted SGP area during construction and operations. After closure and reclamation, the scenic integrity at the SGP would slowly improve. Access roads under the 2021 MMP would cause similar degradations to scenic integrity caused by the construction of and activities on the Burntlog Route. Under the Johnson Creek Route Alternative, the change to scenic integrity would be less evident, because existing roadways would be improved rather than new roadway segments built. However, as there are residences along the existing Johnson Creek Route, there may be more viewers to experience these changes.

Social and Economic

Construction and operation of the SGP would provide jobs and income for both individuals directly employed for the SGP, as well as for other individuals whose employment and incomes would be indirectly or induced by SGP’s activities. Most of these employment and income impacts would support Idaho residents, of which a portion would be Valley and Adams counties residents. Given the local area’s population and current low unemployment conditions, the SGP would result in an in-migration of up to 200 individuals and another 230 dependents for SGP-related employment opportunities. Project-related employment opportunities would have the potential to affect the labor supply for other local employers needing to backfill open positions.

The potential for socioeconomic impacts to the local area’s economy and social conditions would primarily result from the new in-migrant population. The potential influx of new residents (especially those that would be non-SGP employees) may increase the demand and supply of housing and housing affordability within the local area. Other in-migration effects would include potential impacts on school enrollment, telecommunications, infrastructure, government services, and transportation. It also is expected that there could be potential for “boom and bust” impacts on the local area economy if there are insufficient alternative employment opportunities when SGP operations end.

Compared to the 2021 MMP, the Johnson Creek Route Alternative would have substantial increased construction and O&M costs. However, due to its longer construction period (five years instead of three years) and the operating phase’s extended duration, the Johnson Creek Route Alternative’s resulting socioeconomic impacts (i.e., employment, income, population, housing, public services, and government revenue impacts) would be expected to be marginally higher than those identified under the 2021 MMP.

The potential for other adverse impacts to the local area’s economy would be relatively limited. This is due to both the limited extent and remote location of SGP’s expected resource impacts. In addition, recreational opportunities would be available elsewhere in the analysis area for recreationists displaced by SGP’s activities. As a result, these other SGP-related impacts generally would not result in future visitation changes or other impacts to the local area’s overall economy but could affect specific outfitters’ access to the SGP area.

Once in operation, annual government tax revenue benefits from SGP operations are estimated to total $61.7 million. Perpetua is projected to pay $29.4 million in taxes annually. The other $32.3 million would be paid by SGP support businesses and employees. The federal government is expected to receive most of the total tax revenues resulting from operations. Federal tax receipts during the SGP operations phase are projected to be $51.6 million annually. The state and local tax revenues generated are projected to be
$10.1 million per year. Most of these taxes would be received by the State of Idaho. Local tax revenues paid by Perpetua are projected to average $0.3 million per year. Local property taxes may be used to fund local schools, local governments, local law enforcement, fire protection, local roads, and other public services. The extent that the SGP-related increase in state and local tax revenues would result in a net benefit to Valley County’s public services would depend on the extent that they offset increases in costs to provide public services.

The SGP would result in other benefits and costs besides those identified above. The primary purpose and benefit of the SGP action alternatives for the owner/operator would be mineral extraction. Although there are some construction and operational differences between the two action alternatives, their total future revenues would be approximately the same.

**Environmental Justice**

There are no environmental justice minority or low-income communities in the SGP area. However, the SGP area is within the traditional subsistence range of Tribal communities with environmental justice concerns including the Nez Perce Tribe, Shoshone-Bannock Tribes, and Shoshone-Paiute Tribes. Tribal members are more susceptible to be impacted by local area resource changes due to both their use of the SGP area and their long-established cultural connections and attitudes to the local area resources. As a result, many of the SGP-related resource impacts would likely be perceived by Tribal members to have a greater and more long-term adverse impact than that by non-tribal users. For these reasons, Tribal members have a greater potential to be affected than the general population under both action alternatives.

**Special Designations**

**Wilderness**

No structures or human facilities would be developed inside the FCRNRW for the SGP. SGP operations would affect soundscapes, natural dark skies, and natural wildlife distribution within the FCRNRW, impacting the untrammeled quality of wilderness. The SGP would result in emissions that could affect air quality in the FCRNRW. However, emissions would be below NAAQS thresholds. Under the 2021 MMP, construction and use of the Burntlog Route near the FCRNRW boundary could increase noise and lights in adjacent wilderness areas. Use of the Johnson Creek Route under the Johnson Creek Route Alternative would eliminate these impacts. However, the volume of traffic and potential delays along Johnson Creek Route could result in forest visitors avoiding FCRNRW trailheads accessed from Stibnite Road (CR 50-412). Indirectly, recreation use in recommended wilderness areas and other areas of the FCRNRW could increase.

**Wild and Scenic Rivers**

**Impacts to WSR Free-Flowing Conditions**

No impacts to WSR free-flowing conditions are anticipated under either action alternative.

**Impacts to WSR Water Quality**

The 2021 MMP may impact water quality in Burntlog Creek as a result of increased sedimentation from the Burntlog Route construction, winter maintenance, and increased traffic from heavy vehicles. Under the Johnson Creek Route Alternative, Burntlog Creek would not be adversely impacted as the Burntlog Route would not be built. However, increased heavy vehicle traffic could increase sedimentation rates and
therefore decrease water quality in Johnson Creek due to use of Johnson Creek Road for all SGP-related traffic under the Johnson Creek Route Alternative.

**Impacts to Outstandingly Remarkable Values (ORVs)**
Under either alternative, the Heritage ORV of Johnson Creek may be adversely affected by the upgrade of the existing transmission line or the upgrade of Johnson Creek Road, which could potentially impact historic properties located in the vicinity. Under the 2021 MMP, the fish ORV of Burntlog Creek may be adversely impacted by increased sedimentation into fish spawning habitat in the creek.

**Impacts to Wild, Scenic, or Recreational Classification**
Under the 2021 MMP, the wild segment of Burntlog Creek would be adversely impacted by noise and visual effects from the extension, widening, and mine traffic usage of Burnt Log Road (FR 447). The recreational segment of Burntlog Creek could be adversely impacted if a proposed borrow source (i.e., gravel quarry) is sited at the only road access to the recreational segment of this creek.

**Inventoried Roadless Area**
The analysis of effects on roadless character focuses on the wilderness attributes of naturalness; undeveloped character; outstanding opportunities for solitude and primitive types of recreation; special features and values; and manageability which inform impacts to roadless area characteristics.

Construction of SGP facilities, access roads, and utilities would remove vegetation, alter topography, and modify fish and wildlife habitat within IRAs. Construction and operation of the SGP under the 2021 MMP would directly impact the Meadow Creek, Horse Heaven, Black Lake, Burnt Log, Caton Lake, and Reeves Creek IRAs. The Johnson Creek Route Alternative would have a reduced impact on IRAs. Under the Johnson Creek Route Alternative, improvements and use of only the Johnson Creek Route for mine access would eliminate impacts within the Black Lake and Burnt Log IRAs and within portions of the Meadow Creek IRA associated with the Burntlog Route.

**Research Natural Area**
SGP activities would be located downgradient of streams that flow through RNAs or would be in watersheds that do not contain streams that flow through RNAs. There would be no changes to water chemistry, temperature, or quality in the stream segments that flow through the RNAs.

Under the 2021 MMP, reconstructing approximately three miles of Burnt Log Road (FR 447) for the Burntlog Route would remove vegetation within 100 to 3,100 feet of the Chilcoot Peak RNA. Interim reclamation and vehicles could provide opportunities for non-native plant species to become established and spread into the RNA. There would be loss of the Chilcoot Peak RNA research and ecological process values if and where non-native plant species become established. Increased human activities could increase the risk of human ignited fires. Changes in the fire regime could result in a loss of research and ecological process values within the Chilcoot Peak RNA.

Under the 2021 MMP, installation of culverts on the Burntlog Route could change the movement of sediment, woody debris, and other organic material. Culverts could change water quantity or hydrologic connection and indirectly ecological processes in areas adjacent to the Chilcoot Peak RNA. The extent and duration of where there could be changes to ecological processes within Chilcoot Peak RNA is unknown.
The Burntlog Route would not be constructed under the Johnson Creek Route Alternative and would retain the existing ecological process values of the Chilcoot Peak RNA.

**Tribal Rights and Interest**

Either action alternative would cause disturbances that may impact tribal resources and would adversely affect tribal rights and interests. Locations of resources important to the Tribes identified through consultation and in the tribal ethnographic studies are not publicly disclosed due to confidentiality but are known to be present in the analysis area. Tribal fishing, hunting, and plant gathering activities occurred for millennia in this area, as supported by the archaeological record, known usual and accustomed fishing places, and descendant Tribes that continue to use the analysis area and exercise their rights to harvest and gather resources from their traditional places.

Construction and operation of the SGP would directly and indirectly effect tribal resources through physical impacts during construction, through visual impacts due to alteration of the landscape, as well as through audible elements that would impact solitude and tribal use of the analysis area, for example during spiritual practices and resource harvesting. Consultation with the Tribes would be ongoing; therefore, if there are additional discoveries of cultural significant sites or resources during or post construction, formal government-to-government consultation would occur.

Tribal access to the Operations Area Boundary would be restricted during the SGP’s construction, operations, and closure and reclamation phases, preventing tribal members from exercising their off-reservation rights to hunt, gather, and pasture on unoccupied federal lands, access streams and springs, and to fish in usual and accustomed places, for a period of 20 years.

The SGP would impact endangered salmon, other fish species, and essential fish habitat. Harm to fish, wildlife, and habitat would in turn impact availability and harvestability of these resources by Tribes at their usual and accustomed fishing places and traditional hunting and gathering places. Although the action alternatives differ in the acres of habitat affected for fish, wildlife, and plant species, there would be an impact to the availability and harvestability of tribal resources caused by the SGP. There are also concerns that the SGP would impact the Tribes’ fisheries restoration efforts. The Forest Service has therefore concluded that the SGP would have adverse impacts to tribal rights and interests under either the 2021 MMP or the Johnson Creek Route Alternative.

      2.6.2 Processing Method ....................................................................... 2-129
      2.6.3 Facility Locations ........................................................................... 2-130
      2.6.4 Transportation and Access Road Alternatives ................................ 2-131
      2.6.5 Water Management Alternatives .................................................. 2-132
   2.7 Agency Preferred Alternative ................................................................. 2-133
   2.8 Summary Comparison of Alternatives .................................................. 2-134

3.0 AFFECTED ENVIRONMENT ....................................................................... 3-1
   3.1 Introduction ................................................................................................. 3-1
      3.1.1 Scope of Analysis ........................................................................... 3-2
      3.1.2 Relevant Laws, Regulations, Policies, and Plans .............................. 3-2
      3.1.3 Existing Conditions ........................................................................ 3-2
   3.2 Geologic Resources and Geotechnical Hazards ....................................... 3-3
      3.2.1 Introduction .................................................................................. 3-3
      3.2.2 Geologic Resources and Geotechnical Hazards Area of Analysis .... 3-3
      3.2.3 Relevant Laws, Regulations and Policy ............................................ 3-3
      3.2.4 Affected Environment .................................................................... 3-5
   3.3 Air Quality .................................................................................................. 3-29
      3.3.1 Introduction .................................................................................. 3-29
      3.3.2 Air Quality Area of Analysis ......................................................... 3-29
      3.3.3 Relevant Laws, Regulations, Policies, and Plans .............................. 3-33
      3.3.4 Affected Environment .................................................................... 3-38
   3.4 Climate Change .......................................................................................... 3-61
      3.4.1 Introduction .................................................................................. 3-61
      3.4.2 Climate Change Area of Analysis ................................................... 3-61
      3.4.3 Relevant Laws, Regulations, Policies, and Plans .............................. 3-61
      3.4.4 Affected Environment .................................................................... 3-62
   3.5 Soils and Reclamation Cover Materials .................................................. 3-72
      3.5.1 Introduction .................................................................................. 3-72
3.6 Noise ........................................................................................................................................ 3-87
  3.6.1 Introduction ....................................................................................................................... 3-87
  3.6.2 Noise Area of Analysis ...................................................................................................... 3-87
  3.6.3 Relevant Laws, Regulations, Policies, and Plans .............................................................. 3-87
  3.6.4 Affected Environment ....................................................................................................... 3-90
3.7 Hazardous Materials ............................................................................................................... 3-92
  3.7.1 Introduction ....................................................................................................................... 3-92
  3.7.2 Hazardous Materials Area of Analysis ............................................................................ 3-93
  3.7.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-93
  3.7.4 Affected Environment ....................................................................................................... 3-95
3.8 Surface Water and Groundwater Quantity ........................................................................... 3-101
  3.8.1 Introduction ....................................................................................................................... 3-101
  3.8.2 Water Quantity Resources Area of Analysis .................................................................. 3-101
  3.8.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-104
  3.8.4 Affected Environment ....................................................................................................... 3-105
3.9 Surface Water and Groundwater Quality ............................................................................. 3-139
  3.9.1 Introduction ....................................................................................................................... 3-139
  3.9.2 Water Quality Resources Area of Analysis .................................................................... 3-139
  3.9.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-140
  3.9.4 Affected Environment ....................................................................................................... 3-146
3.10 Vegetation ............................................................................................................................. 3-213
  3.10.1 Introduction ....................................................................................................................... 3-213
  3.10.2 Vegetation Resources Area of Analysis ....................................................................... 3-213
  3.10.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-216
  3.10.4 Affected Environment ....................................................................................................... 3-216
3.11 Wetlands and Riparian Resources ....................................................................................... 3-243
  3.11.1 Introduction ....................................................................................................................... 3-243
  3.11.2 Wetlands and Riparian Resources Area of Analysis ..................................................... 3-243
  3.11.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-243
  3.11.4 Affected Environment ....................................................................................................... 3-246
3.12 Fish Resources and Fish Habitat ......................................................................................... 3-259
  3.12.1 Introduction ....................................................................................................................... 3-259
  3.12.2 Fisheries and Aquatic Habitat Resources Area of Analysis ........................................ 3-259
  3.12.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-263
  3.12.4 Affected Environment ....................................................................................................... 3-265
3.13 Wildlife and Wildlife Habitat (Including Threatened, Endangered, Candidate, and Sensitive Species) ........................................................................................................... 3-326
  3.13.1 Introduction ....................................................................................................................... 3-326
  3.13.2 Wildlife and Wildlife Habitat Area of Analysis .............................................................. 3-326
  3.13.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-327
  3.13.4 Affected Environment ....................................................................................................... 3-336
3.14 Timber Resources ................................................................................................................ 3-381
  3.14.1 Introduction ....................................................................................................................... 3-381
  3.14.2 Timber Resources Area of Analysis .............................................................................. 3-382
  3.14.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-382
  3.14.4 Affected Environment ....................................................................................................... 3-385
3.15 Land Use and Land Management ......................................................................................... 3-397
  3.15.1 Introduction ....................................................................................................................... 3-397
  3.15.2 Land Use and Land Management Area of Analysis ..................................................... 3-398
  3.15.3 Relevant Laws, Regulations, Policies, and Plans ............................................................ 3-398
  3.15.4 Affected Environment ....................................................................................................... 3-400
3.16 Access and Transportation .................................................................................................. 3-405
  3.16.1 Introduction ....................................................................................................................... 3-405
3.16.2 Access and Transportation Area of Analysis ................................................................. 3-405
3.16.3 Relevant Laws, Regulations, Policies, and Plans ......................................................... 3-407
3.16.4 Affected Environment .................................................................................................. 3-408

3.17 Heritage Resources .......................................................................................................... 3-415
   3.17.1 Introduction .............................................................................................................. 3-415
   3.17.2 Heritage Resources Area of Analysis ................................................................. 3-418
   3.17.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-420
   3.17.4 Affected Environment ............................................................................................ 3-423

3.18 Public Health and Safety ................................................................................................ 3-431
   3.18.1 Introduction .............................................................................................................. 3-431
   3.18.2 Public Health and Safety Area of Analysis .......................................................... 3-431
   3.18.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-432
   3.18.4 Affected Environment ............................................................................................ 3-432

3.19 Recreation ......................................................................................................................... 3-437
   3.19.1 Introduction .............................................................................................................. 3-437
   3.19.2 Recreation Resources Area of Analysis ............................................................... 3-437
   3.19.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-437
   3.19.4 Affected Environment ............................................................................................ 3-439

3.20 Scenic Resources ............................................................................................................. 3-449
   3.20.1 Introduction .............................................................................................................. 3-449
   3.20.2 Scenic Resources Area of Analysis ....................................................................... 3-449
   3.20.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-449
   3.20.4 Affected Environment ............................................................................................ 3-453

3.21 Social and Economic Conditions .................................................................................... 3-458
   3.21.1 Introduction .............................................................................................................. 3-458
   3.21.2 Social and Economic Conditions Resources Area of Analysis ......................... 3-459
   3.21.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-459
   3.21.4 Affected Environment ............................................................................................ 3-460

3.22 Environmental Justice .................................................................................................... 3-470
   3.22.1 Introduction .............................................................................................................. 3-470
   3.22.2 Environmental Justice Area of Analysis ............................................................... 3-471
   3.22.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-471
   3.22.4 Affected Environment ............................................................................................ 3-473

3.23 Special Designations ........................................................................................................ 3-477
   3.23.1 Introduction .............................................................................................................. 3-477
   3.23.2 Special Designations Resources Area of Analysis ............................................. 3-477
   3.23.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-477
   3.23.4 Affected Environment ............................................................................................ 3-485

3.24 Tribal Rights and Interests ............................................................................................... 3-497
   3.24.1 Introduction .............................................................................................................. 3-497
   3.24.2 Tribal Rights and Interests Resources Area of Analysis ...................................... 3-498
   3.24.3 Relevant Laws, Regulations, Policies, and Plans ................................................. 3-498
   3.24.4 Affected Environment ............................................................................................ 3-504

4.0 ENVIRONMENTAL CONSEQUENCES ............................................................................. 4-1

4.1 Introduction ......................................................................................................................... 4-1
   4.1.1 Effects Analysis Indicators and Methodology of Analysis .................................... 4-1
   4.1.2 Impact Assessment .................................................................................................... 4-2
   4.1.3 Mitigation for Impacts ............................................................................................... 4-3
   4.1.4 Irreversible and Irretrievable Commitments of Public Resources ......................... 4-3
   4.1.5 Short-term Uses versus Long-term Productivity ..................................................... 4-4
   4.1.6 Forest Plan Consistency and Potential Amendments .......................................... 4-4

4.2 Geologic Resources and Geotechnical Hazards ............................................................... 4-4
   4.2.1 Impact Definitions and Effects Indicators and Methodology .................................. 4-4
   4.2.2 Direct and Indirect Effects ....................................................................................... 4-5
   4.2.3 Mitigation Measures ................................................................................................. 4-21
4.11.4 Irreversible and Irretrievable Commitments of Public Resources ........................................ 4-324
4.11.5 Short-term Uses versus Long-term Productivity ................................................................. 4-324

4.12 Fish Resources and Fish Habitat .......................................................................................... 4-325
  4.12.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-325
  4.12.2 Direct and Indirect Effects ............................................................................................... 4-326
  4.12.3 Mitigation Measures ....................................................................................................... 4-385
  4.12.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-385
  4.12.5 Short-term Uses versus Long-term Productivity ........................................................... 4-386

4.13 Wildlife and Wildlife Habitat ............................................................................................... 4-387
  4.13.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-387
  4.13.2 Direct and Indirect Effects ............................................................................................... 4-388
  4.13.3 Mitigation Measures ....................................................................................................... 4-459
  4.13.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-459
  4.13.5 Short-term Uses versus Long-term Productivity ........................................................... 4-460

4.14 Timber Resources ............................................................................................................... 4-461
  4.14.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-461
  4.14.2 Direct and Indirect Effects ............................................................................................... 4-463
  4.14.3 Mitigation Measures ....................................................................................................... 4-471
  4.14.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-471
  4.14.5 Short-term Uses versus Long-term Productivity ........................................................... 4-472

4.15 Land Use and Land Management ....................................................................................... 4-473
  4.15.1 Impact Definitions and Effects Indicators and Methodology .......................................... 4-473
  4.15.2 Direct and Indirect Effects ............................................................................................... 4-473
  4.15.3 Mitigation Measures ....................................................................................................... 4-482
  4.15.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-482
  4.15.5 Short-term Uses versus Long-term Productivity ........................................................... 4-483

4.16 Access and Transportation .................................................................................................. 4-483
  4.16.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-483
  4.16.2 Direct and Indirect Effects ............................................................................................... 4-485
  4.16.3 Mitigation Measures ....................................................................................................... 4-500
  4.16.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-500
  4.16.5 Short-term Uses versus Long-term Productivity ........................................................... 4-500

4.17 Heritage Resources .............................................................................................................. 4-501
  4.17.1 Impact Definitions, Effects Analysis Indicators, and Methodology ................................. 4-501
  4.17.2 Direct and Indirect Effects ............................................................................................... 4-504
  4.17.3 Mitigation Measures ....................................................................................................... 4-511
  4.17.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-512
  4.17.5 Short-term Uses versus Long-term Productivity ........................................................... 4-512

4.18 Public Health and Safety ..................................................................................................... 4-513
  4.18.1 Impacts Definitions and Effects Indicators and Methodology ......................................... 4-513
  4.18.2 Direct and Indirect Effects ............................................................................................... 4-515
  4.18.3 Mitigation and Monitoring ............................................................................................. 4-528
  4.18.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-528
  4.18.5 Short-term Uses versus Long-term Productivity ........................................................... 4-528

4.19 Recreation Resources .......................................................................................................... 4-529
  4.19.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-529
  4.19.2 Direct and Indirect Effects ............................................................................................... 4-530
  4.19.3 Mitigation Measures ....................................................................................................... 4-564
  4.19.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-564
  4.19.5 Short-term Uses versus Long-term Productivity ........................................................... 4-565

4.20 Scenic Resources .................................................................................................................. 4-565
  4.20.1 Impact Definitions and Effects Analysis Indicators and Methodology .............................. 4-565
  4.20.2 Direct and Indirect Effects ............................................................................................... 4-567
  4.20.3 Mitigation Measures ....................................................................................................... 4-591
  4.20.4 Irreversible and Irretrievable Commitments of Public Resources ................................... 4-591
  4.20.5 Short-term Uses versus Long-term Productivity ........................................................... 4-592
5.0 CUMULATIVE EFFECTS ............................................................................................................... 5-1

5.1 Introduction ............................................................................................................................... 5-1
  5.1.1 Cumulative Effects Areas .................................................................................................... 5-1
  5.1.2 Past and Present Actions .................................................................................................... 5-3
  5.1.3 Reasonably Foreseeable Future Actions ........................................................................... 5-8

5.2 Geologic Resources and Geotechnical Hazards ........................................................................ 5-9
  5.2.1 No Action Alternative ........................................................................................................ 5-9
  5.2.2 Action Alternatives ........................................................................................................... 5-10

5.3 Air Quality .................................................................................................................................. 5-11
  5.3.1 No Action Alternative ........................................................................................................ 5-11
  5.3.2 2021 MMP ........................................................................................................................... 5-11
  5.3.3 Johnson Creek Route Alternative ...................................................................................... 5-14

5.4 Climate Change ........................................................................................................................... 5-14
  5.4.1 No Action Alternative ........................................................................................................ 5-15
  5.4.2 Action Alternatives ........................................................................................................... 5-17

5.5 Soils and Reclamation Cover Materials ....................................................................................... 5-17
  5.5.1 No Action Alternative ........................................................................................................ 5-17
  5.5.2 Action Alternatives ........................................................................................................... 5-18

5.6 Noise ......................................................................................................................................... 5-18

5.7 Hazardous Materials .................................................................................................................... 5-19
  5.7.1 No Action Alternative ........................................................................................................ 5-20
  5.7.2 Action Alternatives ........................................................................................................... 5-20

5.8 Surface Water and Groundwater Quantity ................................................................................... 5-20

5.9 Surface Water and Groundwater Quality ..................................................................................... 5-21
  5.9.1 No Action Alternative ........................................................................................................ 5-21
  5.9.2 2021 Modified Mine Plan .................................................................................................. 5-22
  5.9.3 Johnson Creek Route Alternative ...................................................................................... 5-22

5.10 Vegetation: General Vegetation Communities, Botanical Resources, and Non-native Plants .......................................................................................................................... 5-22
  5.10.1 No Action Alternative ....................................................................................................... 5-22
  5.10.2 Action Alternatives ........................................................................................................... 5-24
5.11 Wetlands and Riparian Resources ............................................................... 5-25
  5.11.1 No Action Alternative........................................................................ 5-25
  5.11.2 2021 MMP....................................................................................... 5-26
  5.11.3 Johnson Creek Route Alternative .......................................................... 5-26
5.12 Fish Resources and Fish Habitat ................................................................. 5-26
  5.12.1 No Action.......................................................................................... 5-27
  5.12.2 2021 MMP....................................................................................... 5-27
  5.12.3 Johnson Creek Route Alternative .......................................................... 5-28
5.13 Wildlife and Wildlife Habitat including Threatened, Endangered, Proposed, and
  Sensitive Species .......................................................................................... 5-29
  5.13.1 No Action.......................................................................................... 5-30
  5.13.2 2021 MMP....................................................................................... 5-30
  5.13.3 Johnson Creek Route Alternative .......................................................... 5-31
5.14 Timber Resources ................................................................................... 5-31
  5.14.1 Forest Management........................................................................... 5-31
  5.14.2 Mineral Exploration and Mining Activities ................................................. 5-31
  5.14.3 Transportation Projects ...................................................................... 5-32
  5.14.4 Hazardous Fuels Reduction and Noxious Weed Control Projects .............. 5-32
  5.14.5 No Action Alternative........................................................................ 5-32
  5.14.6 Action Alternatives ........................................................................... 5-32
5.15 Land Use and Land Management .............................................................. 5-33
  5.15.1 No Action Alternative........................................................................ 5-33
  5.15.2 Action Alternatives ........................................................................... 5-33
5.16 Access and Transportation ........................................................................ 5-34
  5.16.1 No Action Alternative........................................................................ 5-34
  5.16.2 Action Alternatives ........................................................................... 5-34
5.17 Heritage Resources .................................................................................. 5-35
  5.17.1 No Action Alternative........................................................................ 5-37
  5.17.2 Action Alternatives ........................................................................... 5-37
5.18 Public Health and Safety .......................................................................... 5-37
  5.18.1 No Action Alternative........................................................................ 5-37
  5.18.2 Action Alternatives ........................................................................... 5-37
5.19 Recreation .................................................................................................. 5-38
  5.19.1 No Action Alternative........................................................................ 5-38
  5.19.2 2021 MMP....................................................................................... 5-38
  5.19.3 Johnson Creek Route Alternative .......................................................... 5-39
5.20 Scenic Resources ..................................................................................... 5-39
  5.20.1 No Action Alternative........................................................................ 5-39
  5.20.2 Action Alternatives ........................................................................... 5-40
5.21 Social and Economic Conditions .............................................................. 5-40
  5.21.1 No Action Alternative........................................................................ 5-40
  5.21.2 Action Alternatives ........................................................................... 5-41
5.22 Environmental Justice ............................................................................. 5-41
  5.22.1 No Action Alternative........................................................................ 5-41
  5.22.2 Action Alternatives ........................................................................... 5-42
5.23 Special Designations ................................................................................ 5-42
  5.23.1 Wilderness ....................................................................................... 5-42
  5.23.2 Wild and Scenic Rivers ...................................................................... 5-44
  5.23.3 Inventoried Roadless Areas ................................................................. 5-45
  5.23.4 Research Natural Areas ..................................................................... 5-47
5.24 Tribal Rights and Interests ...................................................................... 5-48
  5.24.1 No Action Alternative........................................................................ 5-49
  5.24.2 Action Alternatives ........................................................................... 5-50
6.0 CONSULTATION AND COORDINATION ................................................................. 6-1

1.0 PURPOSE OF AND NEED FOR ACTION

1.1 Introduction

The United States (U.S.) Department of Agriculture Forest Service (Forest Service) has prepared this supplemental draft environmental impact statement (SDEIS) in compliance with the National Environmental Policy Act (NEPA) and other relevant federal laws and regulations. This SDEIS discloses the potential environmental effects of the alternatives considered for the Stibnite Gold Project (SGP or the Project) proposed by Perpetua Resources Idaho Inc. (Perpetua) in central Idaho. This document discloses the direct, indirect, and cumulative environmental effects of the Proposed Action and the Action Alternative. More than one federal agency is involved with the SDEIS for the SGP. The Forest Service, specifically the Payette National Forest (PNF), is the lead agency in the preparation of this document (40 CFR 1501.5). The Boise National Forest (BNF) is participating, as well as cooperating agencies including the U.S. Army Corps of Engineers (USACE), U.S. Environmental Protection Agency (EPA), Idaho Governor’s Office of Energy and Mineral Resources (OEMR), Idaho Department of Lands (IDL), Idaho Department of Environmental Quality (IDEQ), and Valley County, Idaho.

This SDEIS was prepared in response to a modified Plan of Restoration and Operations (Plan) for the SGP. The Forest Service received the original SGP Plan in 2016, (Midas Gold Idaho, Inc. [Midas Gold] 2016a) for review and approval in accordance with regulations at 36 Code of Federal Regulations (CFR) 228 Subpart A. A revised Plan, also known as ModPRO1, was submitted to the Forest Service in 2019 (Brown and Caldwell 2019a). A further modified Plan, also known as ModPRO2, was initially submitted in December 2020 with a revised submittal in October of 2021 (Perpetua 2021a). Midas Gold changed their name to Perpetua Resources Ltd (Perpetua) in February 20213. The SGP proposes mine operations on federal, state, and private lands located in Valley County, Idaho.

A draft EIS (DEIS) evaluating five alternatives based on the revised Plan was published August 2020. The further modified mine plan intends to reduce new surface disturbance and anticipated environmental impacts while providing revised descriptions and predicted environmental effects to be considered in the EIS. In addition, comments received on the DEIS recommended that a supplemental DEIS should be prepared for various reasons. Therefore, the Forest Service determined that a SDEIS is warranted and two of the previous action alternatives (August 2020 DEIS Alternatives 1 and 3) were eliminated from further consideration (see Section 2.6 for discussion about alternatives dismissed from detailed analysis).

Additional documentation describing the rationale for developing a SDEIS, the analyses of the effects of the alternatives considered (i.e., August 2020 DEIS), public involvement, and other relevant documents may be found within the Project record located at the Forest Service’s Payette National Forest Supervisor’s Office, 500 North Mission Street, McCall, Idaho.

---

1 Associated project documents may reference the Revised Plan as the ModPRO.
2 Associated project documents may reference the Modified Plan as the ModPRO2.
3 Documents provided by Perpetua prior to the February 2021 name change will still be cited and referenced as Midas Gold.
1.2 Stibnite Mining District History

Prospecting in this region of Idaho began in the 1890s. Gold and antimony mineralization was discovered in the Stibnite area with the first mining claims staked in 1914 (Midas Gold 2016a). The claimants organized the Meadow Creek Silver Mines Company and began minor underground mining in 1919 developing what would become the Meadow Creek Mine, now referred to as the Hangar Flats area. Multiple mining companies considered the Meadow Creek Mine but found the gold/silver/antimony mineralization too difficult to process in milling circuits of the time. Underground development work continued until 1927 when the property was optioned by the Yellow Pine Company.

The Yellow Pine Company invested in a major expansion of the Meadow Creek Mine which, by 1929, included an enlarged camp and a road to connect the mine with the town of Yellow Pine. Expansion of the underground mine from its original portal continued, with other adits driven to gain underground access into other parts of the property including the North Tunnel, Monday Tunnel, and Cinnabar Tunnel. A new camp was built at the location of these two later tunnels south of the current Yellow Pine pit. Additional surface facilities were constructed at Monday Camp including housing, shops, assay facilities, an air strip, and a post office.

In order to provide power for the Meadow Creek and Monday mine camp and facilities, the Yellow Pine Company constructed a reservoir on the East Fork of Meadow Creek in 1930 and installed a wooden pipe and steel penstock between the reservoir and a hydroelectric plant built on Sugar Creek.

Ongoing metallurgical testing of the Meadow Creek Mine ore lead to the construction of a 150-ton per day pilot mill in 1931 at Meadow Creek Camp.

The Meadow Creek Mine was the largest antimony producer in the U.S. and a major gold/silver producer in Idaho. Milling and mining continued at the Meadow Creek Mine until 1938 (Midas Gold 2016a), when the Yellow Pine Company property was taken over by the Bradley Mining Company (BMC).

After 1938 BMC focused on development of an open pit mine at the Yellow Pine deposit which contained higher gold values and lower antimony grades than at the Meadow Creek Mine. Ore was extracted from pits on the east and west sides of the East Fork South Fork Salmon River (East Fork SFSR) and hauled south in trucks from the Yellow Pine open pit to the mill at the Meadow Creek Mine. The mill was expanded from 200 to 400-tons per day capacity and renamed the Stibnite Mill. Mill tailings were initially released into Meadow Creek and later into a tailings impoundment adjacent to the mill.

Beginning in 1939, the federal government began purchasing mineral commodities, including antimony and tungsten, considered to be of strategic importance. The U.S. Geological Survey (USGS) and Bureau of Mines supported detailed exploration of the Yellow Pine deposit with the discovery of economic values of tungsten in 1941. With the federal government's wartime interest in both antimony and tungsten produced from the Yellow Pine deposit, BMC expanded mine operations and upgraded the Stibnite Mill to produce a tungsten concentrate in addition to antimony and gold/silver concentrates. Expansion of the mining at the Yellow Pine deposit included enlarging the open pit along with underground mining and diversion of the East Fork SFSR in a tunnel, called the Bailey Tunnel, which discharged the river water into Sugar Creek (Mitchell 2000). By this time, fish passage to the upward reaches of the East Fork SFSR became impassable due to the development of the Yellow Pine deposit and open pit.
During World War II, BMC continued to expand mining and milling operations at the Meadow Creek Mine. As employment at the mine increased, the Meadow Creek camp grew into the town of Stibnite and included homes, recreational facilities, school, hospital, general store, and other commercial facilities. Two other neighborhoods were also established along lower Fiddle Creek and Midnight Creek. Idaho Power Company built a power line to Stibnite in 1943 which allowed expansion of the Stibnite Mill and provided additional power to support mining and community demands. By the end of the war, the tungsten ore in the Yellow Pine pit was exhausted and lesser tungsten mineral production continued for a time from a placer operation downstream of the Yellow Pine pit.
The tailings storage area west of the mill reached capacity in 1946. A large tailings dike was built south of
the mill in the Meadow Creek valley. Meadow Creek was diverted in order to contain more tailings.
Between 1946 and 1952, BMC deposited an estimated four million tons of tailings in this storage facility.
In 1947 BMC constructed an antimony smelter at the Stibnite Mill to process the antimony concentrate.
Subsequently, the antimony price dropped, and operations of the Yellow Pine Mine and Stibnite Mill and
Smelter were shut down in the 1950s. The Bailey Tunnel diversion of the East Fork SFSR was
abandoned, and the East Fork SFSR was allowed to flow over the south edge of the Yellow Pine pit
forming a pit lake. Meadow Creek was rerouted over the BMC tailings impoundment, resulting in erosion
of the tailings. Residents living in the valley moved out and over time the mine and town buildings in the
valley were abandoned or moved to other locations (Petersen 1999). Although exploration work
continued into 1955 after active mining ceased in 1952, it did not trigger the resumption of mining.

In the 1970s, the technology of cyanide heap leaching of low-grade gold/silver ores was developed by the
U.S. Bureau of Mines and this raised renewed interest in many former gold production districts including
Stibnite. Superior Oil Company (Superior) conducted geological, geophysical, and geochemical
investigations from 1974 to 1977 to evaluate the potential for heap-leach oxide gold and silver in the
West End and adjacent Stibnite deposit, which led to permitting of the open pit West End Mine with the
Forest Service and mine operations by Superior commenced in 1982. An on-off, cyanide heap leach
facility that included five lined leach pads, solution ponds, and a gold/silver recovery plant was built north
of the former Stibnite Mill in the Meadow Creek Valley west of East Fork SFSR. Between 1982 and 1996
more than six million tons of ore were leached in this facility. After gold/silver was extracted from the ore
it was rinsed of its cyanide content and removed from the leach pads. This "spent" ore was hauled to the
former Stibnite Mill tailings storage facility and spread over the top of the fine-grained tailings. This area
was called the Spent Ore Disposal Area (SODA) and included a diversion of Meadow Creek out of the
old tailings area.

Mobile Oil Corporation purchased Superior in 1984 and suspended operations of the West End Mine in
1985 but continued to leach previously mined ore. The West End Mine and leach facilities were
purchased by Pioneer Metals Corporation (Pioneer) in 1986 and were operated by Pioneer until 1991.

Between 1988 and 1992 Hecla Mining leased some of the BMC claims and developed an open pit gold
mine just north of the Yellow Pine pit called the Homestake pit. Initially ore from the pit was leached at
the Pioneer on-off leach facility under a tolling agreement between the companies. In 1990 Hecla
constructed its own leach pad and plant near Stibnite which operated until 1992. The Hecla mine and
leach areas were reclaimed between 1991 and 1993.

Beginning in 1991 the former Pioneer operations were operated by a number of other mining companies
who developed other deposits including the Stibnite and Garnet Creek pits. All mining and leaching
operations in the Stibnite area ceased in 1996.
1.3 Comprehensive Environmental Response, Compensation, and Liability Act Background

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), also known as Superfund, was enacted by Congress in 1980 and amended in 1986, to respond to pollution and the threats posed to human health and the environment from the release, or imminent threat of a release, of hazardous substances. The law authorizes short-term removal actions requiring prompt response and long-term remedial responses at sites, including those listed on EPA's National Priorities List (NPL). CERCLA provides that the potentially responsible parties for releases of hazardous substances pay the costs to investigate and remEDIATE contaminated sites.

The Stibnite Mine Site (CERCLIS [Comprehensive Environmental Response, Compensation and Liability Information System] #9122307607, the Site) was assessed and proposed to be added to the NPL in 2001. Key state and congressional leaders supported funding the cleanup of the Site but opposed the stigma of adding the site to the NPL, thus the Site was not listed. Before 2001, some mining operators at the site conducted activities to reduce the release of hazardous substances. Since 2001, the Forest Service has conducted multiple projects under its CERCLA authority to reduce releases at the Site. The current owner of the site, Perpetua, has proposed to renew mining activities with the proposed SGP intended to address certain impacts associated with the legacy mining as described in Chapter 2 of this SDEIS. The SGP activities would be conducted under applicable mining law and regulations without connection to CERCLA.

In January 2021, Perpetua and affiliates entered into an Administrative Settlement Agreement and Order on Consent (ASAOC) with the EPA and the Forest Service under CERCLA to conduct cleanup of certain conditions at the Site, these areas are mostly outside of and not included in the proposed mining project.

As described in Section 1.2, the mining, milling, smelting, and leaching activities in the district left behind impacts including underground mine workings, multiple open pits, development rock dumps, mill tailings deposits, cyanidation heap leach pads, neutralized (spent) heap leach ore piles, a mill and smelter site, three town sites, camp sites, a washed-out earthen dam (with its associated erosion and downstream sedimentation), haul roads, an abandoned water diversion tunnel, an airstrip, and other disturbances.

Releases of hazardous substances at the Site are documented in multiple studies. Currently, there are ongoing releases of hazardous substances, pollutants, and contaminants to surface water and groundwater at the site including elevated concentrations of antimony, arsenic, copper, lead, mercury, and cyanide. Most notable are elevated concentrations of arsenic and antimony. Past mining activities have also caused alterations to stream configurations and habitat including formation of the Yellow Pine pit lake, sediment and tailings deposits, development rock dumps, and channel diversions.

In the early 1980s spent ore from on/off leach pads was purposely placed over fine-grained tailings deposited in the valley from earlier operations, known as the Bradley Tailings. This feature referred to as the Spent Ore Disposal Area (SODA), was intended to cover the Bradley tailings and prevent their erosion. In the 1990s the mine operator Stibnite Mine Inc. entered into an Administrative Order on Consent (AOC) with EPA to divert stream flow and stabilize the Bradley Tailings/SODA disposal area to improve water quality in Meadow Creek, but the company did not complete the AOC scope of work. In
1998, a new AOC was signed between Mobil Oil Corporation, EPA, and the Forest Service to stabilize and reclaim the Bradley Tailings/SODA area. This work included construction of two diversion channels, lining an old diversion channel to reduce seepage, closing a pond, covering exposed tailings, restoring more natural stream channel features, and reclaiming the area with vegetation. This work was completed in 1999.

Pursuant to its CERCLA authorities, the Forest Service engaged in multiple remediation projects in the district to further reduce impacts from the legacy mining activities. In 2002, the Forest Service removed tailings from a pond and soils located at the former smelter stack area. The material was placed in a repository located at the Bradley NW development rock dump. The Meadow Creek floodplain was reconstructed in the former pond area. In 2004 and 2005, the Forest Service reconstructed Meadow Creek directly downstream of Smelter Flats. This included the removal of tailings from the channel and depositing this material in a new containment cell located on the SODA. The new channel banks were revegetated with willow plants and the old channel was backfilled and reclaimed. In 2009, the Forest Service regraded and covered a portion of the remaining tailings at Smelter Flats to prevent further erosion and exposure risk.

With the signing of the 2021 ASAOC, the parties to the Agreement plan to address certain legacy mining impacts under CERCLA that would not otherwise be addressed by the proposed SGP activities by Perpetua outside the project footprint. The ASAOC includes three primary phases. Phase 1 includes several “time critical removal actions” (TCRAs) consisting of stream diversion ditches designed to avoid contact of water with sources of contamination, and removal of approximately 325,000 tons of development rock and tailings from locations in Meadow Creek or East Fork SFSR that are currently impacting water quality. Phase 1 also includes baseline studies of conditions at five historic mine adits where mine water is discharging. Implementation of removal actions to address the adits is optional under the ASAOC. The purpose of these studies is to collect information to inform potential future CERCLA removal actions at these locations. In addition, Perpetua conducted a biological assessment, Clean Water Act evaluation, and a cultural resource survey to support Phase 1 activities. Phase 1 activities would be accomplished regardless of the status and potential approval of the SGP and is scheduled to be completed between 2021 and 2025. Perpetua is providing $7.5 million in financial assurance for the Phase 1 scope of work.

When all work in Phase 1 is completed, and if approvals and permits have not been obtained by Perpetua for the SGP, the company, upon approval by the agencies, may elect to perform activities in the optional Bridge Phase described in the ASAOC. These activities would potentially include additional water diversions, capping or covering of mine waste in place, and targeted removal of additional mine waste materials to improve water quality. The Bridge Phase would be completed within a year of the agencies’ acceptance of the work plan for this phase if Perpetua and the Agencies elected to implement the activities.

Optional Phases 2 and 3 would be conducted if elected by Perpetua and approved by the agencies. The work would consist of “Non-time Critical Removal Actions” (NTRCAs) and would only be performed by Perpetua if it has obtained approval for the proposed SGP. Phase 2 would consist of further planning and implementing potential removal actions at the five adits studied in Phase 1. Phase 3 would consist of a synoptic study of two reaches of the East Fork SFSR to identify areas for implementation of additional
removal actions in locations identified in the ASAOC Statement of Work and agreed to by the parties that would not be subject to mining and reclamation activities under the SGP in effect at that time. Because these phases are optional, phases 2 and 3 are not considered reasonably foreseeable by the EPA and therefore are not included as cumulative or connected actions within this environmental impact statement (EIS).

1.4 Stibnite Gold Project Overview

The 2021 Modified Mine Plan (2021 MMP) proposes use of the surface of National Forest System (NFS) lands in connection with operations authorized by the U.S. mining laws within the Operations Area Boundary. The 2021 MMP provides details for the construction, operation, reclamation, and closure of a gold, silver, and antimony mine. The following elements are integral to the 2021 MMP:

- Mine pit locations, areal extents, and mining and backfilling methods
- Transportation on existing and proposed roads
- Pit dewatering, surface water management, and water treatment
- Ore processing
- Lime generation plant
- Tailings Storage Facility (TSF) construction and operation
- TSF Buttress construction methods
- Water supply needs and uses
- Management of mine impacted water and stormwater runoff
- Electrical transmission lines
- Stibnite Gold Logistics Facility (SGLF)
- Road maintenance facility
- Surface and underground exploration
- Worker housing facility

1.5 Operations Area Boundary

The SGP Operations Area Boundary, associated access roads, and off-site facilities are located in Valley County, Idaho. The Operations Area Boundary is situated approximately 98 miles by air and 146 miles by road northeast of Boise; approximately 44 air miles and 68 miles by road northeast of Cascade; and approximately 10 air miles and 14 miles by road east of the village of Yellow Pine, Idaho (Figure 1.5-1). Activities described in the 2021 MMP would occur within approximately 820 acres of private lands (including approximately 535 acres of patented mining claims owned or controlled by Perpetua), approximately 2,372 acres of NFS lands, 13 acres of federal land administered by the Bureau of Reclamation, and 62 acres of public lands administered by the State of Idaho.
1.6 Purpose And Need

1.6.1 Purpose and Need for Federal Action

The Forest Service’s purpose is to consider approval of Perpetua’s proposed use of the surface of NFS lands in connection with operations authorized by the U.S. mining law as first described in the Plan submitted September 2016, then refined in 2019 (Brown and Caldwell 2019a), and further modified in 2021 as the 2021 MMP (Perpetua 2021a). The Forest Service’s need for action is to ensure that the proposed occupancy and use of NFS lands is consistent with statutory and regulatory requirements. For purposes of this environmental analysis, the agency is assuming the proposed uses would be able to be authorized under existing regulatory authorities. However, the agency will need to evaluate the eventual applications for rights of way to make a final determination.

The need for action is to:

- Consider approval of Perpetua’s 2021 MMP for development of the SGP to mine gold, silver, and antimony deposits that, where feasible, would minimize adverse environmental impacts on NFS surface resources; and ensure that measures are included that provide for mitigation of environmental impacts and reclamation of the NFS surface disturbance.

1.6.2 USACE’S Purpose and Need

Perpetua’s 2021 MMP includes the discharge of dredge and fill material into waters of the U.S. (WOTUS), including wetlands. Accordingly, the USACE, pursuant to Section 404 of the Clean Water Act (CWA), will review the SGP and render a decision to either issue, issue with special condition, or deny a permit for the Project. As a cooperating agency the USACE intends to use this EIS process and document for evaluating compliance with its responsibilities under NEPA and the CWA Section 404(b)(1) Guidelines. As part of its review, the USACE is required by the CWA to independently consider and express the activity’s underlying purpose and need from Perpetua’s (the applicant) and the public’s perspectives (33 CFR 325).

From the USACE’s perspective, the basic purpose for the SGP is to extract gold, silver, and antimony from ore. Under the CWA Section 404(b)(1) Guidelines (40 CFR 230), the USACE uses the basic project purpose to determine if a project is “water dependent.” A project is water dependent if it must be located in, or be close to, a special aquatic site, including wetlands, to fulfill its basic purpose. The USACE has determined that mining gold, silver, and antimony ore is not a water-dependent activity. The overall project purpose is to mine gold, silver, and antimony from ore deposits associated with the SGP. This overall project purpose will be used for evaluating practicable alternatives under the 404(b)(1) guidelines. The 404(b)(1) analysis will be completed by the USACE following the receipt of public comments on both this SDEIS and Perpetua’s application for a Department of the Army (DA) permit for the SGP.

1.7 Federal Decision Framework

The U.S. mining laws (30 U.S.C. 21-54), govern the exploration and development of minerals on public lands. Locatable minerals operations on NFS lands are subject to regulations found at 36 CFR 228 subpart A. Locatable mineral operations are to be conducted so as to, where feasible, minimize adverse environmental impacts on National Forest surface resources (36 CFR 228.8). In prospecting, locating, and developing the mineral resources, all persons must comply with the rules and regulations covering the National Forests (16 U.S.C. 478). All functions, work, and activities on NFS lands in connection with prospecting, exploration, development, mining, or processing of mineral resources and all uses reasonably incident thereto, including roads that are constructed and maintained in connection with development and mining of mineral resources, are operations authorized by the U.S. mining laws (36 CFR 228.3(a)).

The Forest Service is the lead agency in the preparation of this document (40 CFR Part 1501.5). The USACE is a federal cooperating agency with decisions to be made based on this environmental analysis consistent with the NEPA. Other federal, state, and local agencies are also participating in this review as cooperating agencies as noted in Section 1.1.

1.7.1 Forest Service Decisions

The Payette Forest Supervisor, as the responsible official acting on behalf of the lead agency, has determined that preparation of an EIS is required because approving the 2021 MMP may have significant impacts on the human environment (40 CFR Part 1501). The Payette Forest Supervisor will make the following decisions:

- Whether to approve the 2021 MMP as submitted, or any alternative considered in detail in the final EIS (FEIS).
- Whether to amend the Payette Forest Plan (FEIS and Record of Decision for the Revised Payette Land and Resource Management Plan, 2003 is incorporated by reference). One or more project-specific amendments to the forest plan would be required.

The Boise Forest Supervisor will make the following decisions:

- Whether to amend the Boise Forest Plan (FEIS and Record of Decision for Revised Boise Land and Resource Management Plan, 2010 is incorporated by reference). One or more project-specific amendments to the forest plan would be required.

The Payette and Boise Forest Plans provide direction relevant to the 2021 MMP and its alternatives through forest-wide plan components and management areas. Management Areas (MAs) in the SGP area include the following:

**Payette National Forest**

- Management Area 13 Big Creek/Stibnite

---

4 Forest plan amendments are evaluated under the 2012 Planning Rule per 36 CFR Part 219.17(b)(2), which requires all forest plan amendments initiated after May 9, 2012, to use the 2012 Planning Rule.
Boise National Forest

- Management Area 17 North Fork Payette River
- Management Area 19 Warm Lake
- Management Area 20 Upper Johnson Creek
- Management Area 21 Lower Johnson Creek

Amendments to the Payette and Boise Forest Plans would be required to approve the 2021 MMP or the Johnson Creek Route Alternative. A forest plan may be amended at any time. The responsible officials (Boise and Payette Forest Supervisors) have the discretion to determine whether and how to amend the plan(s) and to determine the scope and scale of any amendment. A plan amendment is required to add, modify, or remove one or more plan components. The proposed removal of the below identified forest plan Standards would be one-time amendments to the current forest plans and would be project-specific and apply only to the SGP. These amendments would be made according to the 2012 Planning Rule (36 CFR Part 219.13) and will comply with the direction in both forest plans relating to Standards.

Opportunities for public participation and notification regarding the forest plan amendments will be combined with the public participation and notification processes used for project planning at 36 CFR Part 218 for this EIS (36 CFR 219.13). The project-specific amendments for the SGP may have effects directly related to 2012 planning rule’s substantive requirements regarding sustainability (Section 219.8), plant and animal community diversity and persistence of native species (Section 219.9), multiple use (Section 219.10), timber (Section 219.11), and others.

Forest Plan amendments, summarized in Table 1.7-1, could be needed in four resource topics, depending on the action alternative selected, to allow the SGP to be consistent with the Payette and Boise Forest Plans.

</table>
For further information pertaining to meeting forest plan consistency requirements, please see the Forest Plan Consistency Analysis by resource in Chapter 4. Substantive requirements (219.8 through 219.11) that are directly related to plan direction being modified through proposed Forest Plan amendments are described in Appendix A. Determinations can be based on adverse, as well as beneficial, effects (36 CFR 219.13(b)(5)(i)). Plan amendments that apply to a specific project can use the analysis prepared for the project as documentation (36 CFR 219.13(b)(1)). For each proposed amendment described in Appendix A, the location of the relevant analysis in the SDEIS is identified.

### 1.7.2 USACE Decisions

The USACE, under Section 404 of the CWA, will review the Project and either issue, issue with special conditions or deny a permit for the Project. The USACE regulates the discharge of dredged and/or fill material into WOTUS, including wetlands (Section 404 of the CWA). The 2021 MMP would place dredged and/or fill material in WOTUS as regulated under Section 404 of the CWA. A CWA Section 404 permit is required for the discharge of dredged and/or fill material into jurisdictional WOTUS (33 CFR Part 323).

In accordance with the CWA Section 404(b)(1) guidelines (40 CFR Part 230), the USACE may permit only the least environmentally damaging practicable alternative while considering cost, logistics, and technology. The USACE has determined that potentially jurisdictional WOTUS, including wetlands, are

present that may be impacted by the Project. These waters are described in the “Wetlands and Riparian Resources” section of Chapter 3.

### 1.7.3 Key Permits Necessary to Implement the Plan of Operations

To implement the 2021 MMP and activities described in this EIS, Perpetua would need to obtain (or renew) permits and licenses. Table 1.7-2 is a list of the key permits likely required to implement the 2021 MMP or the action alternative.

### 1.8 Tribal Participation

The government-to-government relationship between federal agencies and federally-recognized tribes is a special relationship based on tribal sovereignty. The Forest Service is conducting government-to-government consultation with these federally recognized tribes: the Nez Perce Tribe, the Shoshone-Paiute Tribes, and the Shoshone-Bannock Tribes. The Forest Service requested scoping input from the tribes through letters dated May 31, 2017 (Shoshone-Paiute Tribes), June 1, 2017 (Shoshone-Bannock Tribes), and June 6, 2017 (Nez Perce Tribe). The Forest Service presented the SGP and initiated consultation during government-to-government meetings (Nez Perce Tribe May 23, 2017; Shoshone-Bannock Tribes July 26, 2017; and Shoshone-Paiute Tribes April 13, 2017). The Forest Service offered the Tribes cooperating agency status but the Tribes declined. Since then, numerous meetings, calls, and communications have occurred. Government-to-government consultation will continue throughout the process. Details of this consultation are included in Chapter 6 of this SDEIS.

Table Source: Perpetua 2021a
1.9 Scoping and Public Engagement

The Forest Service published a notice of intent (NOI) to prepare an EIS for the SGP in the Federal Register June 5, 2017. The NOI initiated a 45-day scoping period which ended July 20, 2017. During this time period, the Forest Service conducted five public meetings, including in-person meetings in Cascade, McCall, Yellow Pine, and two in Boise, Idaho. A legal notice was published in *The Idaho Statesman*, Boise, Idaho (the newspaper of record), and *The McCall Star News*, McCall, Idaho June 1, 2017.

The PNF received a total of 536 submissions during public scoping. The Scoping and Issues Summary Report can be viewed here: https://www.fs.usda.gov/project/?project=50516.

A notice of availability (NOA) for the DEIS was published in the Federal Register August 20, 2020. The NOA initiated a 60-day comment period; in response to requests for extension, a 15-day extension was granted for public comments on the DEIS. In total, approximately 10,000 submissions were received during the 75-day comment period in response to the DEIS. During that time, a virtual, on-line Project information room provided SGP data for review such as posters, documents, and figures; due to the COVID-19 pandemic, in-person public meetings were not held. In addition, DEIS reference documents were available via a linked document on the Project webpage, except for information held as confidential per Forest Service procedures. The issues evaluated in this SDEIS are derived from public comments originally made during the public scoping period and summarized in the SGP Scoping and Issues Summary Report issued in January 2018 (AECOM 2018). In that document, the comments received during scoping from agencies and the public were summarized into categories, which became the basis for defining issues and indicators. After the public comment period for the SGP DEIS, Midas Gold (now Perpetua) revised the Plan to address potential impacts and public concerns. The comments received on the SGP DEIS were reviewed as additional scoping input during development of this SDEIS.

Additional details regarding public involvement and public scoping are provided in Chapter 6, Section 6.1, Public Participation Summary.

1.10 Issues

Using the comments from public and agency scoping, the Forest Service, in coordination with cooperating agencies, developed a list of resource concerns and topics to address in this SDEIS. For each issue, indicators were created to describe, compare, and contrast the effects of the Proposed Action and alternatives carried forward for detailed analysis.

1.10.1 Significant Issues

The regulations implementing NEPA require federal agencies to develop and evaluate alternatives to Proposed Actions that involve unresolved conflicts concerning alternative uses of available resources (40 CFR 1501.2). Significant issues are those which are used to formulate alternatives to the Proposed Action and to develop mitigation measures. The following significant issues were identified for the SGP and are listed below with indicators which measure and compare potential effects. Significant issues are analyzed in depth in the EIS (40 CFR 1501.7(a)(2)) and may be a cause/effect relationship between the Proposed Action and a significant impact (Forest Service Handbook [FSH] 1909.15 chap. 12.41 [Forest Service 2015a]).
1.10.1.1 Fish Resources and Fish Habitat

Construction and operation of mine infrastructure may impact the quality and quantity of water, habitat for Chinook salmon, steelhead, and bull trout. SGP activities may also affect fish behavior and reproductive success and may result in injury or mortality of Chinook salmon, steelhead, and bull trout in the analysis area.

Indicators:

- Changes in stream and lake habitat directly impacted by channel removal (kilometers [km]).
- Change in amount of total useable Chinook salmon Intrinsic Potential (IP) habitat (km).
- Direct loss of Chinook salmon Critical Habitat (km).
- Changes in total useable steelhead IP habitat (km).
- Changes in the length of available bull trout habitat (km).
- Bull trout occupancy probability.
- Changes in access to bull trout lake habitat.
- Direct loss of bull trout critical habitat (km).
- Length of westslope cutthroat trout habitat (km).
- Westslope cutthroat trout occupancy probability.
- Changes in stream peak and baseflow (cubic feet per second [cfs]).
- Changes in water temperature (degrees Celsius [°C]).
- Changes in water chemistry (analysis criteria).

1.10.1.2 Surface Water and Ground Water Quantity and Quality

Construction and operation of mine infrastructure may impact water quality and quantity within the analysis area.

Indicators:

- Mineralized waste generated (tons, closure stabilization, and water chemistry).
- Exposures of ore bodies/potentially acid-generating material (rock and water chemistry).
- Legacy mine tailings and waste rock (rock and water chemistry).
- Methylation rates for mercury (water chemistry).
- Surface water quality (water chemistry and temperature).
- Groundwater quality (water chemistry).
- Stream flow characteristics (daily, seasonal, annual).
- The extent, magnitude, and duration of changes in groundwater levels (feet of drawdown).
1.10.1.3 **Tribal Rights and Interests**

Construction and operation of mine infrastructure may impact access to reserved Tribal rights and resources. Construction and operation of mine infrastructure may impact tribal resources.

**Indicators:**

- Existence of the Nez Perce Tribe Treaties (1855 and 1863).
- Existence of Shoshone-Bannock Treaty (1868).
- Existence of the Shoshone-Paiute Tribes Executive Order.
- Known prehistoric cultural resources and/or traditional use sites impacted by the SGP.
- Presence of traditional cultural properties\(^5\) (TCPs), cultural landscapes\(^6\) (CLs), sacred sites, and tribal resource collection areas that may be physically impacted by ground disturbance.
- Presence of TCPs, CLs, sacred sites, and tribal resource collection areas that may be impacted by visual intrusions caused by SGP components or an increase in audible elements (noise and vibrations).
- Changes in access to TCPs, CLs, sacred sites, and tribal resource collection areas due to the restricted access within the Operations Area Boundary.
- Changes to species viability and/or availability for tribal harvest of culturally important fish, wildlife, and plants.

1.10.1.4 **Wetlands and Riparian Resources**

Construction and operation of mine infrastructure may impact the quantity of wetland acres, impact ecological function, and fragment wetland habitat.

**Indicators:**

- Amount (acres) of wetland and riparian habitat permanently lost through construction of SGP components.
- Amount (acres) of wetland and riparian habitat temporarily lost through construction of SGP components.
- Functional units of high-value wetlands lost due to project construction, as demonstrated using functional assessment method.
- Acres of wetlands that would be affected by new or improved roads.
- Qualitative analysis of effects of wetland and riparian habitat fragmentation in affected areas.
- Amount (acres) of wetlands that would be within the footprint of groundwater drawdown.

---

\(^5\) A TCP, as defined in the NHPA, is a property that is eligible for inclusion on the National Register of Historic Places (NRHP) “because of its association with cultural practices or beliefs of a living community that (a) are rooted in that community’s history and are important in maintaining the continuing cultural identity of the community” (Parker and King 1998).

\(^6\) A CL is defined as a geographic area, including both cultural and natural resources and the wildlife or domestic animals therein, associated with a historic event, activity, or person, or exhibiting other cultural or aesthetic values. CLs are generally one of four types: vernacular, designed, historic site, or ethnographic (NPS 2021).
• Qualitative analysis of estimated changes in water quality parameters based on predictive water modelling in wetland areas.

1.10.1.5 Access and Transportation

Construction and operation of mine infrastructure may impact public access to NFS lands and affect travel routes within the SGP area.

Indicators:

• Number, location, and description of changes in access due to new and improved roadways.
• Amount of new road (miles).
• Change in amount of use (number of trips).
• Changes to current status on motorized mixed use of routes.

Construction, operation, and reclamation may affect traffic volumes, types of vehicles, and patterns of use. Further, it may affect access to public lands as well as public safety during mine construction, operations, and closure and reclamation.

Indicators:

• Miles of roads used by mine vehicles.
• Change in traffic volume.
• Potential number of accidents, both current and projected.
• Change in emergency access.
• Assessment of effectiveness of design features designed to prevent accidents.

1.10.2 Important Resource Related Issues

Other important issues were developed from scoping comments along with Forest Service and cooperating agency review. Though these issues were not identified as ‘significant issues’, they were identified by the public, the Forest Service, and cooperating agencies as relevant considerations. These other important issues help to focus the analysis of environmental effects to the physical, biological, and social resources under consideration. Like significant issues, other important issues use indicators to measure and compare potential effects. Table 1.10-1 presents other important issues discussed in greater detail in Chapter 4.
Table 1.10-1 Important Resource Related Issues

1.10.3 Issues Eliminated and Dismissed from Additional Analysis

NEPA regulations require the agency to identify and eliminate from detailed study those issues that are not significant or that have been covered by prior environmental review, to narrow the scope of the analysis. Reasons for eliminating issues from detailed study include when the issues are related to the following:

- General opinions or position statements not specific to the Proposed Action;
- Items addressed by other laws, regulations, or policies;
- Items not relevant to the potential effects of the Proposed Action, or otherwise outside the scope of this analysis; and/or,
- Items that have no or negligible effects.

1.10.3.1 Changes to the General Mining Law of 1872

Comments received suggested that reforming or changing the Mining Law, as amended, would address potential future environmental impacts. While the Mining Law is fundamentally a law for acquiring property rights, rather than an environmental law, presumably the comments were directed at eliminating the ability to establish property rights and increasing agency discretion to prevent mining. This is dismissed from consideration because making or amending law is an explicit function of Congress and not within the authority of the Secretary of Agriculture.

1.10.3.2 36 CFR Part 251 Land Uses

Comments received questioned why the proposal was not being evaluated for issuance of a special use permit under the 36 CFR 251 Subpart B regulations. The U.S. mining laws (30 USC 21-54) govern exploration and development of minerals on public lands and the Forest Service is responsible for approving plans for such use and occupancy of NFS lands for locatable mineral operations pursuant to 36 CFR 228 Subpart A. As proposed, SGP is a locatable minerals operation authorized by the U.S. mining laws and subject to regulations at 36 CFR 228 subpart A. Pursuant to 36 CFR 251.50(a), such operations are not subject to 36 CFR 251 Subpart B.

1.10.3.3 Executive Orders

Comments received stated opinions that Forest Service should either comply or ignore certain executive orders, such as Executive Order (EO) 13766 (Expediting Environmental Reviews and Approvals for High Priority Infrastructure Projects), 13807 (Establishing Discipline and Accountability in the Environmental Review and Permitting Process for Infrastructure Projects), and EO 13927 (Accelerating the Nation’s Economic Recovery from the COVID-19 Emergency by Expediting Infrastructure Investments and Other Activities). These EOs were revoked by EO 13990 (Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis). Forest Service complies with the requirements of valid EOs when completing NEPA and implementing processes.
1.10.3.4 **Wild and Scenic Rivers**

Comments received stated that if the SGP might jeopardize the eligibility for WSRs designation for a certain river, and the WSR evaluation was not already completed as part of land use planning, a site-specific analysis is required. Eligibility studies have already been conducted. In 1997, the need for a WSR eligibility study on forest lands based on new information and changed conditions was identified and then conducted. The WSR Act states that, in order to be eligible, a river segment must be free-flowing (free of impoundments or diversions) and contain at least one ORV. During this process it was determined that Burntlog Creek was eligible as a recreational segment from the headwaters to the crossing with FR447 and wild from FR447 to the confluence with Johnson Creek with fish as the ORV. Johnson Creek was determined as eligible as a recreational segment with heritage as the ORV.

The South Fork Salmon River (SFSR) was determined as suitable and recommended for designation as a WSR by the BNF and PNF (Forest Service 2003a: Appendix J WSR Suitability Study Report). The ORVs for the recreational segment within the analysis area are botanical, scenic, geology, heritage, and recreation.

Existing or new mining activity on a Forest Service-identified WSR eligible or suitable river segment are subject to regulations in 36 CFR part 228 Subpart A and must be conducted in a manner that minimizes surface disturbance, sedimentation, pollution, and visual impairment (FSH 1909.12, Chapter 84.3). The heritage analysis ([Section 4.17](#)) identified that there would be no adverse effect to the historic transmission line (Line 328), which is the historic property that would be potentially affected along the eligible segment of Johnson Creek. Other historic properties along this segment would be avoided during the transmission line upgrade. There would be no impact to the heritage ORV along this segment. The fish ORV would not be adversely affected associated with the segments of Burntlog Creek identified as eligible as wild or recreational. There is no impairment to the free-flowing characteristics of either segment.

Further, comments stated that a Section 7 analysis under the WSR Act is required to determine whether the SGP would impair the free-flowing character of any impacted WSR. A Section 7 analysis is only completed for a designated WSR; none of the streams or rivers in the analysis area are designated WSRs. Further, a Section 7 analysis is conducted for federal water resources projects (i.e., located below the ordinary high-water mark); therefore, it is not applicable to the SGP.
2.0 ALTERNATIVES INCLUDING THE PROPOSED ACTION

2.1 Introduction

Chapter 2 describes the action proposed by Perpetua in its 2021 MMP submitted in October 2021 (Perpetua 2021a), an additional alternative utilizing another access route, and the No Action Alternative. Each alternative (including the No Action Alternative) would result in different environmental effects, which are analyzed in detail in Chapter 4. In addition, Section 2.6 includes a discussion of other alternatives considered but eliminated from further analysis. Section 2.7 summarizes the Agency Preferred Alternative. Section 2.8 concludes with a comparative summary of the environmental effects.

2.2 Development of Alternatives

2.2.1 Regulatory Setting for Alternatives Development

Alternatives were developed by the Forest Service and the USACE, with input from other cooperating agencies, guided by the NEPA, CWA, and U.S. Department of Agriculture Forest Service regulations (40 CFR 1502.14, 40 CFR 230, and 36 CFR 220.5, respectively), Forest Service Region 4 guidance, and the FSH. The Organic Administration Act, and Forest Service regulations at 36 CFR 228 Subpart A, governing mineral development on NFS lands also provided guidance regarding alternatives development.

2.2.2 Alternatives Screening Criteria

As used in this EIS, an action “alternative” is a complete package of operations, activities, and facilities that comprise a functioning mine project. A complete mining plan has several “component” parts, each necessary to allow production. In many instances, operational components may be further comprised of “subcomponents.” To develop a range of reasonable alternatives, Perpetua’s plan of operations, as supplemented by additional information and clarifications, was separated into components and subcomponents.

Public comments received during scoping provided early input into potential alternatives to the proposed SGP. An iterative review by the Forest Service and cooperating agencies, evaluated these comments to determine whether they were reasonable alternatives to the proposed SGP using four basic screening criteria described below. In addition to alternatives suggested during scoping, the Forest Service, cooperating agencies, and Perpetua also completed an alternatives development and review process. This process incorporated a review of the Plan and included consideration of alternatives Perpetua had already evaluated prior to the submission of their Plan (Midas Gold 2016a, Appendix G). Potential alternatives and component options were screened based upon four criteria:

1. Does the alternative, including a combination of component options, meet the purpose and need of the SGP?
2. Would the alternative or component option potentially reduce environmental effects to at least one resource?

3. Is the alternative or component option technically feasible?

4. Is the alternative or component option economically feasible?

Options not meeting the purpose and need (Section 1.6) were documented and eliminated first. Each remaining option was then evaluated for technical and economic feasibility and potential environmental impacts using the significant impact issues identified through the scoping process (Section 1.10). Infeasible options or options lacking any environmental benefit over the Proposed Action were then eliminated. In addition, options similar in design to an alternative that was carried forward into detailed analysis were screened out to avoid duplication. Section 2.6 provides additional discussion of specific component alternatives and options that were considered but eliminated.

Further review of alternatives after consideration of comments on the DEIS and submittal of a 2021 MMP by Perpetua eliminated certain action alternatives considered in the DEIS (Section 2.6).

Project refinements included in the 2021 MMP: (1) are supported by updated data and analysis that identify opportunities to reduce potential environmental impacts; (2) further ameliorate potential environmental impacts; (3) are informed by public and agency comments on the DEIS, and; (4) align with the NEPA, and all applicable federal, State, and local regulations and permit requirements.

### 2.2.3 Alternatives Overview

As described below, there are two action alternatives and the No Action Alternative. In general terms, these alternatives are:

**No Action Alternative** – The No Action Alternative provides an environmental baseline for comparison of the action alternatives. Under the No Action Alternative, the mining, ore processing, and related activities under the action alternatives, including removal of legacy materials, would not take place. However, existing, and approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue and Perpetua would not be precluded from subsequently submitting another plan of operations for consideration and evaluation pursuant to the General Mining Law of 1872.

**2021 MMP** – The 2021 MMP is based upon Perpetua’s Modified Plan of Operations submitted in October 2021 for the SGP. For access, the 2021 MMP would utilize Warm Lake Road, Johnson Creek Road, and Stibnite Road (comprising the Johnson Creek Route) during construction of the Burntlog Route, then utilize the Burntlog Route for the last year of construction of the mine site through operations and reclamation. The 2021 MMP primarily refines the open pit mining, pit backfill, water management, and closure aspects of the project compared to earlier Plan of Operations submittals.

**Johnson Creek Route Alternative** – The Johnson Creek Route Alternative was developed by the Forest Service and the cooperating agencies to evaluate potential reductions from access related effects. The mining portion of this alternative would be the same as the 2021 MMP. Therefore, the primary focus of the Johnson Creek Route Alternative is consideration of using an existing route, which would require
improvements, for mine access during operations and reclamation instead of a route that under the 2021 MMP requires new road construction in and through IRAs.

### 2.2.4 Components Common to and Primary Differences Between the Action Alternatives

The following mine components would be common to the two action alternatives:

- Mine pit locations, areal extents, and mining and backfilling methods
- Transportation management on existing and proposed roads
- Pit dewatering, surface water management, and water treatment
- Ore processing
- Lime generation
- Tailings Storage Facility (TSF) construction and operation
- TSF Buttress construction methods
- Water supply needs and uses
- Management of mine impacted water and stormwater runoff
- Electrical transmission lines
- Stibnite Gold Logistics Facility (SGLF)
- A road maintenance facility
- Surface and underground exploration
- Stibnite Gold Project worker housing facility

These mine components are described under the 2021 MMP and would remain the same under the Johnson Creek Route Alternative. **Table 2.2-1** provides a summary of the differences between the action alternatives. Because **Table 2.2-1** describes primary differences, not all the components listed above are included in the table.

</table>
### 2.3 No Action Alternative

Under the No Action Alternative, the Plan would not be approved and no mining, ore processing, or related activities would occur, including removal of legacy materials (i.e., SODA and Hecla heap leach) included in the Plan. Previously approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue. In a reasonably foreseeable future action, certain legacy and existing mining impacts would be addressed as directed in the 2021 ASAOC described in Section 1.3, including installation of stream diversion ditches designed to avoid contact of water with sources of contamination and removal of approximately 325,000 tons of development rock and tailings that are currently impacting water quality. These CERCLA response actions would occur under all alternatives considered in this analysis. Under the No Action Alternative, Perpetua would not be precluded from subsequently submitting another plan of operations pursuant to the Mining Law to the Forest Service for subsequent evaluation.

### 2.4 2021 MMP

#### 2.4.1 Overview

The 2021 MMP, the revised Proposed Action, is based on the ModPRO2 (Perpetua 2021a). Mine operations would occur on patented mining claims owned or controlled by Perpetua and on unpatented mining claims and other areas of federal public lands comprised of NFS lands that are administered by the PNF. Supporting infrastructure corridors (access and transmission line) are located on the BNF, IDL, Bureau of Reclamation (BOR), and non-federal lands.

Perpetua proposes to develop a mine operation that produces gold and silver doré, and antimony concentrates from ore deposits associated with their mining claims in the SGP area. The estimated recoverable mineral resource consists of:

- 4.2 million ounces of gold
- 1.7 million ounces of silver
- 115 million pounds of antimony
Development of the mineral resource would include construction of access and haul roads; construction of supporting infrastructure; open pit mining; ore processing; placement of tailings in a TSF; and placement of development rock. New access to the SGP would be provided by the proposed Burntlog Route, which would be a combination of widening the existing Burnt Log Road (FR 447), Thunder Mountain Road (FR 50375), and Meadow Creek Lookout Road (FR 51290) and constructing new connecting road segments of approximately 15 miles (Figure 2.4-1). Development of the Burntlog Route would entail 340.9 acres of new cut and fill activity (including borrow sources) along existing and newly constructed roadways.

To provide electric power for the SGP, an existing powerline would be upgraded and a new transmission line from a new Johnson Creek substation to the mine would be constructed. Additional off-site support facilities to be constructed along access corridors include the SGLF and the Burntlog Access Route Maintenance Facility. The SGLF would house administrative offices, the assay laboratory, and a warehouse while the maintenance facility would be the headquarters for road maintenance and snow removal (Section 2.4.4.9). The proposed facilities and access roads are shown on Figure 2.4-1 and Figure 2.4-2. The Operations Area Boundary shown on Figures 2.4-1 and 2.4-2 is the boundary within which Perpetua would control public access.

The components of the 2021 MMP are described in the following sections in terms of overall land management and affected areas, and project phases: construction; operations; exploration; and closure and reclamation, including post-closure monitoring.

### 2.4.2 Land Management and Affected Areas

Table 2.4-1 provides a summary of land management or ownership by estimated SGP component for the maximum affected area proposed and also includes acreages of new disturbance and re-disturbance by SGP component and ownership.

### 2.4.3 Phases and Timeline

The actions proposed under the 2021 MMP would take place over a period of approximately 20 to 25 years, not including the long-term, post-closure environmental monitoring or potential long-term water treatment. The phases of the SGP are described in subsequent sections and include: (1) Construction (approximately 3 years; Mine Years -3 through -1); (2) Mining and Ore Processing Operations (approximately 15 years; Mine Years 1 through 15)); (3) Surface and Underground Exploration (approximately 17 years, beginning during construction and continuing concurrent with operations; Mine Years -2 through 15); and (4) Closure and Reclamation (Mine Year 16+). Most activities in the Closure and Reclamation period would be completed within five years. However, closure water management and water treatment are expected to continue for as long as 25 years (Mine Years 16 through 40). The environmental monitoring phase would continue for as long as needed to demonstrate that the site has been fully reclaimed. Figure 2.4-3 provides an illustration of the timing of construction and operations activities and the initiation of the closure phase.

Source: Perpetua 2021a

<sup>1</sup> Utilities affected areas include both existing utility corridors and access routes, and new utility corridors and access routes. Some existing utility access routes would be upgraded.

<sup>2</sup> Approximately 65 affected acres associated with temporary surface exploration pads and roads (SGP component) have an unknown land ownership because the exact locations of these exploration areas are not yet known; however, these are included in the PNF SGP subtotal.

<sup>3</sup> Items, subtotals, and totals may not add up to grand total due to rounding.

<sup>4</sup> Approximately 14 acres of land is administered by the PNF but is within the boundary of the Salmon Challis National Forest.

BOR – Bureau of Reclamation; IDL – Idaho Department of Lands
2.4.4 Site Preparation, Access, and Infrastructure

2.4.4.1 Overview

Implementing the 2021 MMP would require construction of surface facilities, haul roads, and water management features. Supporting infrastructure would include transmission lines, substations, communication sites, and access roads. Additionally, removal of some features from past mining activities (legacy mining features) would be initiated during the construction phase. Perpetua would install 15 to 20 temporary trailers on private lands adjacent to the existing exploration camp (located in the proposed ore processing area) to accommodate construction crews; these temporary trailers would be used during site preparation and early construction until the worker housing facility is constructed.

Prior to site preparation and construction of surface facilities, vegetation would be removed from operating areas. Trees, deadwood, shrubs, and slash would be removed, and any remaining vegetation would be grubbed using a bulldozer. The resulting material would be chipped and stockpiled for use as mulch or blended to create a growth media additive. After vegetation removal, growth media would be salvaged and stockpiled. Stockpiles would be stabilized and seeded.

The existing potable water supply system at the exploration camp would be used and expanded for the construction camp. The existing system would be supplemented with deliveries of potable water, if needed. Supplemental water sources (i.e., water deliveries) would be used by personnel in remote construction areas. Sanitation during construction would be provided through the existing sewage treatment system adjacent to the exploration camp. In addition, portable sanitary facilities would be located throughout the SGP and at remote construction areas.

Construction of the Burntlog Route would occur from both ends of the route at the same time on a seasonal basis (May to November), but construction could occur outside of this time period if conditions allow. The southern portion workforce would be housed in three temporary trailer camps located within construction borrow sources or staging areas. The northern portion workforce would be housed at the temporary trailer construction camp at the SGP. Some construction workers could be housed in Cascade, Idaho.

Pre-construction water management activities would include best management practices to reduce erosion and sediment delivery to streams. These water management features could include sedimentation ponds; run-on water diversion ditches, trenches, and/or berms; runoff water collection ditches; silt fence; water bars; culverts; energy dissipation structures; terraces; and other features specified in construction permits. In the second and third years of construction, mine contact water would be generated by stormwater runoff at the West End pit, Yellow Pine pit, TSF embankment, legacy Hecla heap leach, and the SODA, but would be contained as described in Section 2.4.5.10.
2.4.4.2 Growth Media Stockpiles

Suitable growth media within the area proposed for operations would be salvaged following vegetation clearing and moved to growth media stockpiles (GMSs) either within the Fiddle Valley or at the Worker Housing Facility. Other short-term GMSs would be located within the footprint of the TSF. Growth media from the new construction of the Burntlog Route would be stockpiled in the borrow source areas used for construction and widening of the route and in windrows along the edges of fill slopes. GMSs would be stabilized, seeded, and mulched to protect the stockpile from wind and water erosion.

To achieve the reclamation success criteria and offset the growth media deficits, 1.5 million BCY of unconsolidated overburden (chiefly alluvial and glacial materials from Yellow Pine pit) would be stored in the Fiddle GMS to allow use as cover material for reclamation of the TSF, TSF Buttress, and Hangar Flats pit backfill.

2.4.4.3 Access Roads

Warm Lake Road

Warm Lake Road (CR 10-579) is a two-lane (one lane each direction), asphalt-paved roadway with lane markings open year-round to all vehicles from Idaho State Highway (SH) 55 to Warm Lake. The road starts in Cascade at an intersection with SH 55, which is a major north-south transportation corridor. This intersection would be used by all mine-related traffic through all phases of the SGP. The Warm Lake Road continues eastward for approximately 35 miles, ending at Johnson Creek Road (CR 10-413) at Landmark. Warm Lake Road is under the jurisdiction of Valley County. Currently, Valley County does not maintain Warm Lake Road in winter beyond Warm Lake Lodge. With adequate snowpack, an 8-mile segment of the Warm Lake Road route east of Warm Lake Lodge is used as an OSV route, allowing access into Landmark and points beyond.

SGP would need year-round passenger and delivery truck access from the onset of construction through the life of the mine. The Warm Lake Road is suitable for this use in its current condition. Perpetua would conduct wintertime maintenance east of Warm Lake Lodge to ensure safe, year-round access to the sole route of ingress/egress to the SGP for all mine support traffic. This would include snow removal and road sanding, as appropriate, to maintain a safe driving surface. Commitments for wintertime maintenance of Warm Lake Road would be documented in a Road Maintenance Agreement with Valley County.

Perpetua wintertime maintenance and use of Warm Lake Road would result in two changes to current traffic conditions:

- Warm Lake Road east of Warm Lake Lodge would not be available as a recreational OSV route from the start of construction through reclamation of the SGP. To replace this recreational use, a dedicated alternative OSV route would be established from the Warm Lake area to Landmark via the Cabin Creek/Trout Creek drainages and adjacent to the Johnson Creek Road. Establishing this replacement OSV route would minimize the interactions between SGP traffic and recreational traffic in the winter. The proposed OSV route is illustrated in Figure 2.4-4.
• Expanded wintertime public vehicle access on Warm Lake Road east of Warm Lake Lodge would commingle SGP and public travel.

Changes to the SH 55 and Warm Lake Road intersection would improve access for large trucks carrying equipment and supplies to the SGP and would facilitate turns from SH 55 onto Warm Lake Road and from Warm Lake Road back onto SH 55. Any changes proposed to the intersection would need to be approved and implemented by the Idaho Transportation Department (ITD). Recommended changes to the intersection include: the addition of left and right turning lanes (Parametrix 2018a); an intersection modification to accommodate larger trucks; potential relocation of two power poles (HDR Engineering, Inc. [HDR] 2017a); and a modification to the westbound approach at Warm Lake Road to improve the view of traffic coming from the north.

**Johnson Creek Route**

During the initial construction period of the Burntlog Route (approximately 2 to 3 years), mine-related traffic would access the SGP from SH 55, north of the city of Cascade, via Warm Lake Road for approximately 34 miles, then north on Johnson Creek Road (CR 10-413) for approximately 25 miles to the village of Yellow Pine, and from Yellow Pine east approximately 14 miles to the SGP via the Stibnite Road (CR 50-412). The portion of the route that includes Johnson Creek Road and Stibnite Road is known as the Johnson Creek Route. This route is primarily situated topographically adjacent to the valley bottom, paralleling Johnson Creek and then the East Fork SFSR.

Johnson Creek Road is a county-maintained, native-surface road that is open to vehicles with seasonal restrictions due to snow. During the winter, Valley County plows approximately 10 miles of Johnson Creek Road from Yellow Pine south to Wapiti Meadow Ranch and grooms the remaining 17 miles of Johnson Creek Road from Wapiti Meadow Ranch to Warm Lake Road at Landmark for OSV use. Valley County does not plow Warm Lake Road from Warm Lake to Landmark; this section is a designated groomed OSV route.

The Stibnite Road portion of the route is also a county-maintained native surface road, open to all vehicles with seasonal restrictions due to snow. This road is plowed in the winter by Perpetua through an agreement with Valley County. Stibnite Road connects to Thunder Mountain Road on the southeastern portion of the Stibnite site and currently provides seasonal (non-winter) public access through the site.

* Trout Creek Campground north to Wapiti Meadows would be closed for the duration of construction through closure and reclamation under the Johnson Creek Route Alternative.

Surface Management
Private
U.S. Forest Service

Other Data Sources: Perpetua; State of Idaho Geospatial Gateway (INSIDE Idaho); Boise National Forest; Payette National Forest

1 inch = 1.5 miles
when printed at 11x17
Minor surface improvements (such as ditch and culvert repair, adding gravel, winter snow removal, resurfacing if required, and summer dust suppression) would occur on the Johnson Creek Route under the 2021 MMP to reduce sediment runoff and dust generation. However, there would be no road alignment modification or widening of these existing roads along the Johnson Creek Route. The road varies in elevation from approximately 4,750 to 6,700 feet amsl with an average grade of 1.5 to 2 percent with occasional local segments with grade up to approximately 8 percent.

Portions of Johnson Creek Road (i.e., Landmark to Wapiti Meadows) are currently used as a groomed OSV trail during winter and use of the Johnson Creek Route by mine-related construction traffic would conflict with this existing groomed OSV trail. Thus, while the Burntlog Route (described below) is under construction, a temporary 16-foot-wide groomed OSV trail adjacent to Johnson Creek Road between the proposed Cabin Creek Groomed OSV Route and Landmark would be constructed (Section 2.4.4.4 and Figure 2.4-4). However, the OSV trail from Trout Creek Campground to Wapiti Meadows would be closed until construction of the Burntlog Route is complete; once mine traffic moves to that route, then the OSV route would return to Johnson Creek Road and would reconnect Landmark with Wapiti Meadows.

Perpetua has an existing agreement with Valley County for maintenance of Johnson Creek and Stibnite roads, including performing maintenance measures to repair segments that have deteriorated. Appropriate revisions to the road maintenance agreement would be established for use of the Johnson Creek Route as a construction route and to ensure year-round access in accordance with Valley County’s public road easement stipulations. Once construction of the Burntlog Route has been completed (2-3 years), the Johnson Creek Route would no longer be used by mine-related traffic.

**Burntlog Route**

The Burntlog Route would connect the eastern end of Warm Lake Road (at Landmark) to the SGP (to the northeast) by widening and improving approximately 23 miles of existing roads, including the full length of the existing Burnt Log Road (FR 447) and segments of Meadow Creek Lookout Road (FR 51290) and Thunder Mountain Road (FR 50375). The three road segments would be connected with two new road segments totaling approximately 15 miles. Burnt Log Road is currently a native surface road that is open year-round to all vehicles with seasonal restrictions due to snow. The last 0.25 to 0.5 mile of the existing road is closed and motorized traffic prohibited. Meadow Creek Lookout Road is a native surface road, open year-round to all vehicles. The Burntlog Route is primarily situated topographically on mid-slopes and ridgeline.

Improvements on the existing roads that comprise the Burntlog Route include:

- Straightening tight corners to allow for improved safety and traffic visibility;
- Maintaining grades of less than 10 percent in all practicable locations;
- Placing sub-base material and surfacing with gravel;
- Application of a road binding agent in localized segments to suppress dust, increase stability, and reduce sediment runoff;
• Widening the existing road surface (currently approximately 12 feet wide) to a 21-foot-wide travel way (approximately 26 feet including shoulders); and

• Installing side-ditching, culverts, guardrails, and bridges, where necessary, with design features to provide fish passage and limit potential sediment delivery to streams.

**Figure 2.4-5** shows the proposed Burntlog Route, which includes the proposed new road construction. A segment of new road construction for the Burntlog Route would be located on the south side of the Riordan Creek drainage and cross Riordan Creek north of Black Lake. The approximately 5.3-mile road segment would have 12 stream crossings, three of which cross perennial streams. The elevation of this road segment is approximately 8,000 to 8,600 feet and the average grade of this road segment would be 5 to 6 percent. After construction is completed, public use would be allowed on Burntlog Route when other public access roads are blocked by mine operations.

The connection segment between the end of Burnt Log Road and Meadow Creek Lookout Road is approximately 11 miles and would cross Trapper Creek 0.5 miles east of the intersection of Trapper Creek Road (FR 440) and FR 440A and continue northeast towards Black Lake and on to the Meadow Creek Lookout Road. The second connector between the Meadow Creek Lookout Road and Thunder Mountain Road would be approximately 4 miles and links up with Thunder Mountain Road approximately 2 miles south of the SGP. Minor surface improvements (e.g., blading) would occur on the portions of the existing Thunder Mountain Road and Meadow Creek Lookout Road that would not become part of the Burntlog Route to provide a safe road surface for transportation of construction equipment required to build the Burntlog Route. There would be no road alignment modification or widening of the portions of the existing roads that are not part of the Burntlog Route.

Primary SGP access would shift from the Johnson Creek Route to the Burntlog Route near the end of the construction phase. The Burntlog Route would be compliant with all related usage and approval requirements included in 36 CFR Section 228, Part A. The Burntlog Route would avoid environmental and human health and safety risks associated with the Johnson Creek Route which passes through identified areas for avalanches, landslides, and floods. This route would provide another route for SGP ingress/egress, would decrease SGP and public traffic interaction with Yellow Pine and Johnson Creek area residents; and would decrease the potential for spill risk adjacent to fish-bearing streams. Upon completion, the Burntlog Route would serve as an alternative public access route to the Thunder Mountain area for the life of the mine until it is decommissioned following mine reclamation and closure.

**Burntlog Route Borrow Sources, Staging Areas, and Construction Camps**

Up to eight borrow sites would be established along the Burntlog Route (**Figure 2.4-5**) to meet construction and ongoing maintenance throughout the life of the mine and to support decommissioning following mine closure. Additionally, those same eight borrow areas would be utilized for staging of equipment and supplies. Three construction camps would be located within the disturbance created by borrow sources or staging areas. The construction camps would be for trailer parking. Each trailer would need to be equipped with fresh water and sanitary waste storage.

2.4.4.4 Public Access

During construction of the SGP and completion of the Burntlog Route, to the degree practicable, the public would continue to have access on forest roads currently available to the public (Figure 2.4-1). However, current public access through the SGP on Stibnite Road would be restricted for a period of approximately one year while a new through-site public access road is constructed. A new 4-mile long, 12-foot-wide gravel road would be constructed to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road through the SGP (Figure 2.4-2). The road would be constructed on a widened bench on the west side within the Yellow Pine pit, then head south of the Yellow Pine pit, where this road would utilize an underpass to cross under a SGP haul road and continue southward, parallel to and on the east side of the mine haul road on a partially revegetated portion of a former haul road (Figure 2.4-2). Southwest of the ore processing area, the public access road would connect with Thunder Mountain Road and continue toward the worker housing facility, exiting the SGP to the southeast.

During operations, the public access road through the SGP would provide seasonal use, open to all vehicles; access would not be provided in winter when impassable (current county maintenance standards) and signs would inform the public of seasonal and temporary closures. Vehicles passing through the SGP would be required to check-in with mine personnel at the North or South SGP entry points and would receive a safety briefing and would also be required to check-out with SGP personnel upon exiting the SGP. For safety purposes, public access would be separated from other SGP roads by berms, security fencing, and the underpass to allow the public road to pass beneath the mine haul road. No stopping or deviating from the public access road would be allowed. Perpetua would restrict SGP access to any vehicles due to concerns related to public or employee health and safety, such as during road construction and maintenance, blasting, highwall scaling, mining in the immediate area of the road, and similar operations.

Public access would continue along Johnson Creek Road and Burnt Log Road. Total closures of half-day to multiple days could occur during construction work on Stibnite Road between the village of Yellow Pine and the SGP, part of Thunder Mountain Road, and Burnt Log Road.

Public use of the Burntlog Route would provide motorized access to Meadow Creek Lookout Road (FR 51290) and Monumental Summit. Other routes available for public use are shown on Figure 2.4-1.

Public access by foot via existing trails or on roads would be restricted within the Operations Area Boundary shown on Figure 2.4-2. Security personnel, fencing (including wildlife exclusion fencing), and signs would restrict public access to vehicular traffic on the designated public access roadway inside the Operations Area Boundary.

**Warm Lake to Landmark Groomed OSV Trail**

Due to year-round access to the SGP along the Burntlog Route, an existing, approximately 8.5-mile-long groomed OSV trail from Warm Lake to Landmark would be closed for the life of the SGP. To replace this recreational use, a dedicated alternative OSV route would be established from Warm Lake area to Landmark via the Cabin Creek/Trout Creek drainages and Johnson Creek Road (Figure 2.4-4).
Near Warm Lake, an approximately 2-acre parking area would be established west of South Fork Road on FR 474B. A new 3.2-mile groomer access trail would be established from the parking area to the Forest Service Warm Lake Project Camp south of Paradise Valley Road (FR 488) where the groomer would be stored. An approximate 0.1-mile segment would be groomed from the intersection of Paradise Valley Road and FR 488A to Warm Lake Road. The Cabin Creek Road (FR 467) portion of the groomed OSV trail would extend approximately 13 miles to the Trout Creek Campground on Johnson Creek Road. Portions of Cabin Creek Road would require stream crossing improvements, localized road widening, and surface grading to support the OSV route grooming equipment.

**Johnson Creek Groomed OSV Trail**

From Trout Creek Campground to Landmark, an approximately 8-mile temporary groomed OSV trail would be created and maintained on NFS lands adjacent to the west side of Johnson Creek Road (CR 10-413). Portions of the temporary groomed OSV trail would be established using a snowplow wing attachment requiring some vegetation and tree removal to allow for safe snowplowing. In areas where topography and vegetation prevent using the wing attachment to establish the groomed OSV trail, sections would merge with Johnson Creek Road. During construction, the OSV route would include an additional 0.34 of a mile segment east along the Warm Lake Road connecting Johnson Creek Road to Deadwood-Stanley Road (FR579) (Figure 2.4-4).

**Warm Lake Area OSV Connection**

A 16-foot-wide groomed OSV trail would be created and maintained north of Warm Lake Road to connect the southern end of the Cabin Creek Road OSV trail to the Warm Lake Road (FR 579). It would also provide access to North Shoreline Drive (FR 489) from the Cabin Creek Road OSV trail. This 0.3-mile route would be used throughout construction and operations and would require the removal of some vegetation and trees.

**Temporary OSV Closure Trout Creek Campground to Wapiti Meadows**

OSV access would be temporarily halted between Trout Creek Campground and Wapiti Meadows (about 9 miles north of Trout Creek Campground on Johnson Creek Road; Figure 2.4-4) for approximately 2 to 3 years during construction of the Burntlog Route. Once construction of the Burntlog Route has been completed, the Johnson Creek Route would no longer be used by mine-related traffic and the OSV route would be returned to the unplowed Johnson Creek Road and extended northward to provide approximately 17 miles of groomed OSV access between Landmark and Wapiti Meadows. Resumption of OSV access between Trout Creek Campground and Wapiti Meadows would occur following construction of the Burntlog Route.

**2.4.4.5 Traffic**

Traffic associated with SGP construction would occur year-round, depending upon road and weather conditions. Construction-related traffic and material hauling would be most concentrated from May through November, and personnel would be transported primarily using buses and vans. The total estimated annual average daily traffic (AADT) for construction activities driving from SH 55 to the SGLF and between the SGLF and the SGP is listed in Table 2.4-2. Supplies and deliveries for the SGP during
construction would access the SGLF using SH 55 to Warm Lake Road and would use SH 55 through Cascade and other communities along SH 55 south of Cascade including Banks and Horseshoe Bend.

SH 55 to SGLF – State Highway 55 to Stibnite Gold Logistics Facility
SGLF to SGP - Stibnite Gold Logistics Facility to Stibnite Gold Project
HV – heavy vehicle
LV – light vehicle
AADT – annual average daily traffic

The estimated annual average traffic to the SGLF and from the SGLF to the SGP during mining and ore processing operations is also provided in Table 2.4-2. Supplies and deliveries for the SGP during operations would access the SGLF using SH 55 to Warm Lake Road. Approximately two-thirds of all mine-related traffic would originate south of Warm Lake Road and would use SH 55 through Cascade and other communities along SH 55 south of Cascade including Banks and Horseshoe Bend. Approximately one-third of all mine-related traffic originating north of Warm Lake Road would use SH 55 through the communities of Donnelly, Lake Fork, and McCall. Through McCall, mine-related traffic would generally use Deinhard Lane and Boydstun Street. Employees would be encouraged to use company provided shuttle buses as transport to the SGLF from towns along SH 55.

2.4.4.6 Water Use and Water Treatment During Construction

During construction, mine-impacted water would be generated and would require treatment before being discharged to receiving streams. Water treatment plants would be modular, vendor-supplied equipment package skids placed on improved pads with covers and freeze protection for sensitive piping and equipment. Peak capacity on-site for construction water treatment requirements is expected to be 300 gpm with average flows of 18 gpm and 128 gpm during the first and second years of mine site construction, respectively. Water treatment plant residuals would be sent to the TSF for disposal.
2.4.4.7 Transmission Line Upgrades

In order to serve Perpetua’s 60-megawatt (MW) load requirement for the SGP, Idaho Power Company (IPCo) would rebuild or construct 72.8-miles of transmission line and associated facilities (Figure 2.4-6). The existing Cascade to Warm Lake 69-kV transmission line, and much of the Lake Fork to Cascade and the Warm Lake to Yellow Pine 69-kV transmission lines, would be rebuilt to 138-kV clearances and capacity (Perpetua 2021b). A new Johnson Creek Substation would be constructed and a new 9.1-mile, 138-kV transmission line would be built between the new Johnson Creek Substation and the new Stibnite Substation at the SGP. The existing single-phase distribution line between the proposed Johnson Creek Substation and the village of Yellow Pine would remain intact. A new single-phase underground distribution line, within the existing road ROW, would be built along Johnson Creek Road between the Johnson Creek Substation and Wapiti Meadows to the south. The existing 69-kV transmission line between the Cascade Dam and the Cascade Substation would remain unchanged except for tying the two lines into the new Cascade Switching Station. A new 69-kV line would be constructed to connect the Cascade Switching Station to the existing grid to the south.

Changes to the existing IPCo system for SGP operations would include:

- Upgrade approximately 59.1 miles of the existing 12.5-kV and 69-kV transmission lines between the Lake Fork and Johnson Creek substations to 138-kV service. The ROW would be 50 to 100 feet (depending on slope aspect) and existing transmission line support structures would be replaced with taller structures.

- A new approximate 9.1-mile, 138-kV line would be constructed from the Johnson Creek substation to a new substation at the SGP, partially within a former transmission line ROW. The ROW for the new transmission line would be approximately 100 feet wide. At the SGP, transformers would reduce the voltage from 138-kV to 34.9-kV for distribution to facilities through overhead distribution lines or underground conduits.

- Upgrade the substations located at Oxbow Dam, Horse Flat, McCall, Lake Fork, and Warm Lake (Figure 2.4-6).

- A new substation (Johnson Creek substation) approximately 0.7 mile south of the Johnson Creek airstrip on NFS lands would be built to provide low voltage distribution to Yellow Pine and electricity to the SGP (Figure 2.4-6).

- New construction of the Scott Valley and Thunderbolt Tap substations, a new switching substation near Cascade (Cascade switching station), and the removal of the existing Scott Valley substation.

- U.S. Forest Service
• Reroute approximately 5.4 miles of transmission line to avoid the Thunder Mountain Estates subdivision. The reroute would parallel Warm Lake Road for approximately 2.4 miles before crossing onto NFS and IDL land for approximately 1.7 miles. The portion crossing IDL property would require a ROW easement. An additional 1 mile of 69-kV transmission line would be required along Thunder City Road linking the existing transmission line out of Emmett to the reroute. Approximately 2.7 miles of transmission line would no longer be required and would be removed.

• Reroute approximately 0.9 miles of transmission line to approximately 600 feet north of its current location between Cascade and Donnelly to use an old railroad grade on private property and the existing transmission line would be removed.

• Install approximately 3 miles of new underground distribution power along Johnson Creek Road from the Johnson Creek substation south to Wapiti Meadows.

The transmission line extends across lands managed by the BNF, PNF, BOR, IDL, and private lands (Figure 2.4-6). Table 2.4-3 summarizes the transmission line segments by land ownership crossed.

BOR = Bureau of Reclamation
Both temporary and permanent disturbances would be required for the construction of the transmission line and substations. While existing structure locations would be used when possible, the removal and installation of new structures would require temporary disturbance. Where possible, single-pole structures would be installed rather than H-frame structures to minimize the structure disturbance footprint. Table 2.4-4 lists areas permanently disturbed for each transmission line structure type.

**Table 2.4-4  Land Permanently Disturbed for Transmission Line Structures**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Each transmission line structure site needs a construction space large enough to remove the existing structure, excavate structure foundation holes, and install new structure poles and any guys and anchors. Temporary disturbance is based on a 100-foot by 60-foot pad for each structure location. Some temporary disturbance areas would be 100-foot by 100-foot pads. Lands affected during construction by line segment and substations and the land status are listed in Table 2.4-5.

Lands required permanently for Project operations by route segment and land status are listed in Table 2.4-6.

</tbody>
</table>
The transmission line structures would use standardized IPCo structure types, including single-pole and H-frame structures in a variety of configurations. Distribution underbuild is a construction method where the distribution voltage circuit is constructed underneath the transmission circuit to reduce the number of power poles. Single-pole structures would be used in areas where distribution underbuild is present, shorter structure spans are needed, smaller corridors are used, or a limited structural footprint is required. Typical spans for single-pole structures would be approximately 300 feet in length. H-frame structures typically comprise two poles and would be used for areas where longer spans, increased structural capacity, or mountainous terrain is encountered. Typical spans for H-frame structures would be approximately 600 feet in length. Structure heights would vary between 45 and 80 feet depending upon
structure type and terrain. However, structure heights greater than 80 feet could be required in isolated instances.

The estimated number of each type of structure by line segment is available in the Plan of Development (POD) for Electrical Transmission, Stibnite Gold Project (Perpetua 2021b).

**Foundations**

Structure foundations would include direct embedded wood poles. Angle structures and dead-end structures could require the excavation and placement of guy anchors to complete the structure installation, if needed. In locations where guy anchors would not be feasible and designed steel poles would be necessary, structures would be supported by drilled pier caisson foundations.

**Conductors**

Electrical transmission and distribution lines use metallic conductors to allow the flow of current which are designed in a manner that balances current flow, strength, and sagging characteristics. Alternating current (AC) transmission lines use three phases for each transmission circuit. IPCo standards require a minimum ground clearance of 24.5 feet for all new construction of 138-kV transmission lines. Additionally, the transmission lines would include fiber-optic cables and 3/8-inch steel overhead ground wire.

**Overhead Ground Wire and Electrodes**

Overhead ground wires are required to provide a transmission system with protection from the adverse effects of lightning. The shielding of the transmission system would be provided by an optical ground wire, which is a steel-coated, fiber-optic cable that provides the same levels of system protection as steel overhead ground wire, but also includes a core of fiber-optic cables used for communications.

**Distribution Underbuild**

Distribution underbuild (the lower voltage line) would be co-located on the transmission line structures under the primary 138-kV voltage (the higher voltage line).

Distribution underbuild is usually the last remaining conductor to be installed after the transmission conductors, overhead ground wire, and optical ground wire are finished.

**Grounding**

Grounding a transmission line is required to operate and maintain the facility safely. The grounding process is achieved by electrically connecting structure hardware to a ground rod buried within the earth. This electrical connection of hardware allows the safe flow of current and does not allow the build-up of voltage that could cause a mechanical failure or safety concern.

An electrical effects study is required to determine the methods and equipment needed to safely mitigate the site-specific current flows through these adjacent facilities. Typically, all metallic structures within the ROW would be grounded, including buildings, fences, and pipelines. If the electrical effects study determines that structures outside of the ROW require grounding, mitigation measures to safely ground those facilities would be required.
Other Nonelectrical Hardware

For utilities where avian protection and aircraft warnings are required, non-electrical hardware may be installed on the line. This hardware or marking could include bird flight diverters, marker balls, tower lighting, or tower painting. Structures would be marked or protected from avian intersect using the guidelines and methodologies detailed in the Avian Power Line Interaction Committee (APLIC) recommendations. Any Federal Aviation Administration (FAA) requirements would be in accordance with the FAA Circular 70/7460 document, which details the operational requirements for structures exceeding a safe operational elevation in relation to air space.

Access Roads

In addition to the transmission line work detailed above, the existing road network used to access these structures may require maintenance/improvements to allow construction equipment safe access into the power line corridor. While the existing road network proximate to the transmission line ROW would be used to the maximum extent possible, some new service roads (roads used solely by Perpetua or IPCo to access Project facilities) could be needed to reach structure locations without existing access.

Additionally, overland service routes would be required from the existing access road to reach structure locations without current access. These overland service routes would not require blade work (i.e., recontouring). A 14-foot-wide ROW is being requested for the existing/proposed roads outside of the power line corridor ROW to accommodate construction and maintenance equipment. For FR 467, a 16-foot-wide ROW is being requested to accommodate OSV.

During construction, the new section of transmission line between the Johnson Creek substation and the SGP would require major improvements to Horse Heaven Road (FR 416W), NFS Trail 233 (no name), and approximately 4 miles of new spur roads would be constructed. Minor upgrades to Cabin Creek Road (FR 50467) would also be required.

Road maintenance requirements prior to construction would vary depending on the type of road, level of use, and condition of the road. However, maintenance generally would consist of clearing vegetation and rocks, as well as repairing cut and fill slope failures, as necessary, to allow for a 14-foot-wide road surface. In most cases, the roads would be left as close to an undeveloped nature (i.e., two-track road) as possible without creating environmental degradation (e.g., erosion or rutting from poor water drainage). Equipment to perform the required road maintenance would include hand tools (e.g., chainsaws), track driven machines (bulldozers and graders) and crew-haul vehicles (such as 4-wheel-drive pickups and/or off-highway vehicles [OHV; includes all terrain vehicles (ATVs), utility task vehicles (UTVs) and side-by-sides]). Roads would be opened/cleared for use by trucks transporting materials, excavators, drill rigs, bucket trucks, pickup trucks, and crew-haul vehicles. Specific actions, such as installing water bars and dips to control erosion and stormwater, would be implemented to reduce construction impacts and would follow standard designs.

Access road construction and disturbance can typically be summarized into five types of access roads:
**Existing (No Improvement)** – These existing roads provide access to structures and would not require improvement. Minor maintenance activities such as pruning of vegetation for construction vehicle access and applying water to the road to reduce dust may be required.

**Existing (Minor Improvement)** – These existing roads provide access to structures and should not require significant improvement to utilize for construction. Existing road widths typically vary from 14-foot-wide access roads to 24-foot-wide gravel roads with 14 feet being the minimum needed to accommodate construction traffic. Minor maintenance activities such as applying water to the road to reduce dust and improve workability of the soil for blading and compaction, and blading may be required during and after construction to support construction traffic and return the road to a preconstruction condition.

**Existing (Major Improvement)** – These existing roads provide access to the structures and may require major reconstruction work. These roads appear to be in questionable condition and would likely require major reconstruction to support construction traffic. Existing road widths may be as narrow as 8 feet for primitive two-track roads that need reconstruction to widen the driving surface to 14 feet, with curve widening and turnouts added to accommodate construction traffic. Overall disturbance width is estimated to be an average of 20 feet, which includes cut/fill slopes and other impacts associated with reconstruction. Maintenance activities such as applying water to the road, to reduce dust and improve workability of the soil, and blading may be required during and after construction to support construction traffic. Aggregate/crushed rock placement may be required to maintain the existing road.

**New (Overland Travel)** – These roads traverse existing agricultural fields or open areas and are not expected to require grading work to support construction traffic. No permanent road construction is anticipated on these routes, and any earthwork or aggregate imported would be reclaimed after construction. Temporary driving surface is estimated to be 14 feet to accommodate construction traffic. Sections of road that cross wet fields or wetlands may have temporary matting installed to provide a stable surface to support construction equipment without disturbing the ground. Minor work such as grade smoothing at ditches or large rock removal may be required to provide a drivable surface.

**New (Bladed)** – New bladed roads are typically required where the existing ground has a significant cross slope or traverses terrain that needs to be bladed smooth. Construction of the road prism would require excavation and placement of fill material to provide a stable driving surface. The driving surface is constructed to a minimum width of 14 feet and includes curve widening and turnouts to accommodate construction traffic. Overall disturbance width is estimated to be an average of 35 feet, which includes cut/fill slopes and other impacts associated with construction. Earthwork quantities are typically balanced for each road by adjusting the grade to balance material being cut versus filled. Surfacing rock is not typically placed on these roads unless required by stakeholders or needed to support construction traffic.

Table 2.4-7 provides a summary of miles of access roads by route segment and land status.

¹ Totals may not sum correctly due to rounding.

### Substations

IPCo determined there would be a need to increase the 230/138-kV transformer capacities at the Oxbow and Horse Flat substations to support the SGP load. A 20 megavolt amps reactive capacitor bank would also need to be installed at the McCall Substation for voltage support under abnormal (element out of service) conditions. A new 138/69-kV switching substation would be required to be located near Cascade. Several smaller substations along the transmission line from Cascade to Yellow Pine would also need to be upgraded from 69-kV to 138-kV. A 138-kV metering substation would be placed in the Johnson Creek area to feed the village of Yellow Pine and serve as a metering point for the Stibnite 138-kV line. The substations would be operated and maintained by IPCo. Table 2.4-6 provides the area that is needed, by land status, for each of the substations.

Additional details regarding the upgrades needed to existing substations and the construction of new substations are available in the Electrical Transmission POD (Perpetua 2021b).
Periodic inspections of the transmission lines and supporting structures would be required and conducted as described below. Depending on the results of the inspection, maintenance work may be scheduled for immediate follow up (e.g., in the case of imminent failure or safety issues) or follow up in subsequent year(s) (e.g., issues that need to be repaired but do not cause an imminent problem). The activities presented below are considered routine Operation and Maintenance activities. Subject to specific terms, conditions, and stipulations of the ROW grant and reporting requirements contained herein, these activities may be conducted by IPCo as necessary and without prior notification to the Forest Service:

- Routine air patrols to inspect for structural and conductor defects, conductor clearance problems, and hazardous trees. These are typically conducted from a helicopter, and personnel include a pilot and line patrolmen.

- Routine ground patrols to inspect structural and conductor components. A vast majority of such inspections would require either a pickup truck or OHV. Patrols may rely on direct line of-sight and/or binoculars. Patrols are typically conducted in the spring and fall.

- Climbing surveys to inspect hardware or make repairs. Personnel access these structures by pickup, OHV, or on foot.

- Line and structure inspections may also be conducted using unmanned aerial vehicles.

- Structure or conductor maintenance from a bucket truck. Routine cyclical vegetation clearing to trim or remove tall shrubs and trees to prevent encroachment into the minimum vegetation clearance distance consistent with IPCo standards.

- During all vegetation clearing activities, IPCo would ensure there is no disturbance of the soil surface that would create an added risk of erosion, the promotion of the establishment or expansion of invasive species (including noxious weeds), damage to cultural resources, sensitive species, or ESA listed species.

- Removal of hazard trees within, or adjacent to, the ROW that pose a risk of falling into conductors or structures and causing outages or fires. Wood pole inspection and treatment to retard rotting and structural degradation.

- Routine inspection and maintenance of authorized service and access roads (length and width and alignment of road remains the same), such as blading the road to maintain the surface condition and drainage, removing minor physical barriers (i.e., rocks and debris), replacing culverts or rock crossing, and rehabilitating after major disturbances requiring heavy equipment (such as slumping). Heavy equipment would travel and maneuver on existing service and access roads.

- Vegetation removal on service roads to allow the necessary clearance for access and provide for worker safety. Removal is conducted by hand crews using chain saws or by mechanical means. Plants that would not interfere with the safe operation of vehicles and equipment would be left in place.
• Installation of bird protection devices, bird perch discouragers, and relocation or removal of bird nests. Under the authority of the Migratory Bird Treaty Act, the Bald and Golden Eagle Protection Act, or Idaho Code, the appropriate permits would be acquired from the U.S. Fish and Wildlife Service (USFWS) and/or Idaho Department of Fish and Game (IDFG), prior to relocation or removal of nests.

• Reduction of fuel loads around wood poles in fire-prone areas by (1) removal of vegetation within a 20-foot radius and/or treatment with herbicide from the approved Forest Service list by a certified applicator, and in accordance with the Pesticide Use Permit, or (2) application of fire-retardant coating to the base of wood poles. If herbicide is used, IPCo would report to the Forest Service the amount used for Forest Service’s herbicide application yearly report.

• In-kind structure replacement (such as replacing a cross-arm, replacing an insulator, replacing a single wood pole with a single wood or steel pole). A bucket truck and/or other rubber-tired vehicles may be located on or off a road.

• Non-cyclical vegetation clearing to remove saplings or larger trees in the ROW consistent with IPCo standards.

• Structure or conductor maintenance in which earth must be moved, such as for the creation of a landing pad for construction or maintenance equipment.

• Follow-up restoration activities, such as seeding, noxious-weed control, and erosion control. To minimize the potential for wildland fires to damage structures, reseeding activities would not occur within a 20-foot radius around structures.

• Conductor replacement, which requires the use of several types of trucks and equipment and grading to create a safe work area to hang and pull the conductor into place.

Substation maintenance activities would include equipment testing, preventative repair, and procedures for providing continual service and maintaining electrical service. Typical substation maintenance does not require ground-disturbing activity, although ground disturbance could be required to replace damaged equipment, oil containment facilities, or other miscellaneous items.

2.4.4.8 Communication Towers and Repeater Sites

Perpetua installed a microwave relay communications tower in 2013, on private land to the east of the SGP, for communications. The existing communications tower would be upgraded by anchoring the existing tower pad; extending the tower 20 feet in height; upgrading the antenna by adding a dish or second antenna; and installing new high frequency radios capable of increasing bandwidth to 1,000 megabits per second. Alternatively, Perpetua in partnership with IPCo and local communication providers could add fiber optic cable to the transmission line between Cascade and Stibnite. The existing microwave relay tower is shown on Figure 2.4-2.
The existing two-way radio system would need to be expanded at the SGP and along the Burntlog Route to allow rapid communication between equipment operators and ground personnel, and to allow broadcast of emergency messages. The two-way radio system would be supported by a series of repeaters placed on public and private land.

A series of VHF radio repeaters would be placed along the Burntlog Route as needed. The VHF repeaters would be placed near the existing Meadow Creek Lookout and Thunderbolt Lookout communication sites, the new Burntlog Maintenance Facility, and on private parcels at the SGP, as needed. The 10-foot-tall towers on 3-foot by 3-foot concrete pads would be supported by solar panels, support hardware, and a backup battery case. Given their location at existing or proposed facilities, no additional disturbance for equipment installation or access would be required for their construction or maintenance. Each site would be accessed annually (at a minimum) or as required for maintenance. No additional disturbance for equipment installation or access would be required.

A cell tower also would be installed to facilitate area communications. The proposed cell tower would be approximately 60 feet tall and would include surface disturbance of approximately 30 feet by 60 feet (0.04 acre) and utilizing an existing access road. The cell tower location would be near the proposed transmission line alignment upslope of the Hangar Flats pit (Figure 2.4-2).

### 2.4.4.9 Off-site Facilities

Perpetua would require off-site facilities to support mine-related activities. Administrative offices, a transportation hub, and warehousing and assay laboratory would be located at the proposed SGLF, while road maintenance and snow removal activities would be supported by Perpetua from the proposed Burntlog Maintenance Facility.

Additional off-site facilities that would be constructed and operated are described below.

**Stibnite Gold Logistics Facility**

The SGLF would be located along Warm Lake Road on private land (approximately 7 miles northeast of Cascade), with access to SH 55 (Figure 2.4-1). The SGLF would require approximately 25 acres of disturbance to accommodate employee parking, an assay laboratory building, a core sampling logging storage facility, warehouses, laydown yards, equipment inspection areas, a truck scale, and an administration building for Perpetua personnel (Figure 2.4-7). The facility would be surrounded by a security fence. One point of ingress/egress would access office parking and the mine personnel card-entry gate, while another ingress/egress would access the truck yard via a guard shack. The parking and assembly area would accommodate approximately 250 light vehicles for employees using bus or van pooling to the SGP. Perpetua would mandate the use of busing and vans for employee and contractor transportation to the SGP.
Figure 2.4-7
Stibnite Gold Logistics Facility

Stibnite Gold Project
Stibnite, ID

Data Sources: Perpetua 2021a

(See Figure 2.4-1 for location of Stibnite Gold Logistics Facility.)
Perpetua would require supply truck drivers to check in at the SGLF and direct them to either proceed to the SGP or unload at the warehouse for temporary storage and consolidation of their load. A truck scale would be located at the SGLF to verify loads going into or out of the warehouse area. The check-in process would include general safety and road readiness inspection of incoming trucks and equipment being transported to SGP. Heavy equipment transport vehicles would be inspected for items such as presence of weeds, excessive soil on earth moving equipment, safety equipment, installed and maintained engine brake muffling systems, and general safety checks of equipment.

In addition, the Scott Valley substation would be located within the property boundary north of the SGLF, surrounded by a separate security fence.

The SGLF would require a domestic groundwater well to service the facility. This well and associated water right would require permitting through the Idaho Department of Water Resources (IDWR).

**Burntlog Maintenance Facility**

The Burntlog Maintenance Facility would be located on NFS land within a previously disturbed borrow source site 4.4 miles east of the junction of Johnson Creek Road and Warm Lake Road (Figure 2.4-1) and would be accessed via the Burntlog Route with two points of ingress/egress. The facility footprint would be approximately 3.5 acres and would not be fenced. The facility would include three main buildings: a 7,000-square-foot maintenance building; a 7,000-square-foot aggregates storage building; and a 4,050-square-foot equipment shelter (Figure 2.4-8). It would also contain a fuel station, electric generator, propane tank, outdoor storage area, and worker sleeping quarters. It would house sanding/snowplowing trucks, snow blowers, road graders, and support equipment in the equipment shelter or maintenance buildings. The Burntlog Maintenance Facility would require a domestic groundwater well to service the facility. This well and associated water right would require permitting through the IDWR.

This facility would include a double-contained fuel storage area housing three above-ground 2,500-gallon fuel tanks for on-road diesel, off-road diesel, and unleaded gasoline. Additionally, a 1,000-gallon used oil tank would be located inside the maintenance facility and a 1,000-gallon propane tank would be located at the facility for heating.

Additional features of this facility could include covered stockpiles of coarse sand and gravel for winter sanding activities; temporary or emergency on-site housing for road maintenance crews during periods of heavy snow removal needs and other winter maintenance activities; and communications equipment including a tower. This facility could also serve to support snowmobile trail grooming and grooming equipment storage as needed.

**2.4.5 Mine Operations**

The SGP would consist of mining three primary mineral deposits and the re-mining of historical tailings using conventional open pit shovel and truck mining methods. Ore from three open pits (Yellow Pine, Hangar Flats, and West End pits) would be sent to either the crusher, located near the processing plant, or one of several ore stockpiles in various locations within the Operations Area Boundary (Figure 2.4-2; M3 2021). Pre-stripping, or removing the overlying soil and rock (i.e., development rock) to access the mineral deposit, would commence during the construction phase in Mine Year -2. Ore removal and
processing would begin in Mine Year 1 (operations phase) and continue year-round for approximately 15 years. Mine operations would occur in the area of two historical open pit mined areas (Yellow Pine and West End) and one new open pit (Hangar Flats) that includes former underground mining and mineral processing facilities.

In general, ore mined from the three open pits would be hauled directly to the primary crusher area; however, during extended periods when the ore tonnage or ore type from the pits exceed the availability of the ore processing plant, the ore would be stockpiled and processed at a future time. Development rock (also commonly referred to as waste rock) would be hauled to the TSF embankment or placed in one of four destinations: the TSF Buttress or the Yellow Pine, Hangar Flats, and West End open pits once they are mined out.

2.4.5.1 Open Pits

Figure 2.4-2 shows the location and extent of the three pits to be mined. A general sequence for mining, assuming 15 years of mine operations as shown on Figure 2.4-3, would be as follows:

- Yellow Pine pit – Mine Years 1 through 7
- Hangar Flats pit – Mine Years 4 through 7
- West End pit – Mine Years 7 through 12
- Stockpile mining – Mine Years 12 through 15

The Yellow Pine pit would be in the northern portion of the SGP, in the same general location as a historical open pit mining area. The pit would be expanded to include a shallower mining area to the northeast previously mined as the Homestake pit. The East Fork SFSR currently flows through the legacy Yellow Pine pit, forming a small pit lake (Yellow Pine pit lake), when the East Fork SFSR flowed into the pit after it was abandoned in the 1950s.

The West End pit would be in the northeast portion of the SGP, east of and at a higher elevation than the Yellow Pine pit, generally situated between Sugar Creek to the north and Midnight Creek to the south. The West End pit would be in the same general location as historical open pit mining where multiple open pits, mine benches, waste rock dumps, and areas of deep backfill exist. The existing Stibnite pit is within the southern portion of the West End pit, and once expanded would be known as the Midnight pit.

The Hangar Flats pit would be in the central portion of the SGP, generally encompassing steep south and southeast facing slopes and the adjacent Meadow Creek valley floor at the toe of these slopes. Historical mining activity in this area was primarily underground but the proposed pit also would encompass the site of the former Bradley mill and smelter, the Hecla heap leach, and Stibnite Mine Inc. leach pads.
(See Figure 2.4-1 for the Burntlog Maintenance Facility location.)

Source: Perpetua 2021a

amsl = above mean sea level.

Partial dewatering of the open pits would occur prior to and concurrent to renewed SGP mining. Shallow alluvial and deeper bedrock wells would be drilled adjacent to the pits to intercept and pump groundwater before it flows into the pits. During mine operations, groundwater seepage and in-pit surface water runoff would be collected for reuse in the ore processing plant or treated and discharged, according to whether there was a water deficit or surplus at a given time. Additional details on pit water management can be found in Section 2.4.5.10.

### 2.4.5.2 Drilling and Blasting

Drilling and blasting would be used to break ore and development rock in the mine pits (see M3 2021 for additional details). Following drilling, explosives would be used to break rock into fragments that are suitable for loading into equipment. An Explosives and Blasting Management Plan would be prepared as part of the final mine plan. Explosives storage, transport, handling, and use would comply with applicable Department of Homeland Security, Bureau of Alcohol, Tobacco, Firearms and Explosives, Department of Transportation, and Mine Safety and Health Administration (MSHA) regulations.
2.4.5.3 Rock Loading and Haulage

Rock loading and haulage would use a development fleet and a production mining fleet. Mine development excavation required to establish haul truck access roads, access limestone, and pre-stripe pits prior to production mining would use a fleet of medium sized excavators, wheel loaders, and 45-ton articulated trucks. This development fleet would also be used to salvage growth media and support reclamation activities. Production mining would use a conventional diesel truck and shovel fleet consisting of two 28-cubic yard hydraulic shovels, approximately sixteen 150-ton haul trucks, and one 28-cubic yard wheel loader. The wheel loader would be used primarily to load haul trucks during shovel maintenance and to load stockpiled ore as needed. The ore would be hauled directly to the primary crusher or the run-of-mine ore stockpile at the ore processing facilities.

2.4.5.4 Ore Management

Ore from the open pits would be hauled to and placed directly into the ore processing plant, except during periods when the amount or type exceeds the availability of the ore processing plant, the excess ore would be stockpiled in unlined facilities on top or within other mine disturbance areas. Seven long-term ore stockpiles and one short-term stockpile would be used to manage the excess ore (Figure 2.4-2). The long-term ore stockpiles would be located on and near the TSF Buttress and Hangar Flats pit and the short-term stockpiles would be located near the crusher.

Highest-grade ore would be sent directly to the crusher, or to the short-term stockpile area near the crusher where it would likely be processed within a few days. Lower-grade ore would be sent to the long-term ore stockpiles where it would remain for months or longer. Some of the ore sent to the low-grade ore stockpiles would be re-handled during active mine operations, and some would be re-handled and processed once open pit mining has ceased. If metal prices do not support processing of some of the long-term stockpiles, the stockpiled material would be covered as part of TSF Buttress closure activities (Section 2.4.7).

Three long-term ore stockpiles would be on the TSF Buttress on the north side of the valley. Two stockpiles would be adjacent to the Hangar Flats pit and extended onto the pit footprint after it is backfilled. A stockpile within the West End pit footprint would temporarily store ore mined during West End Road development and pre-stripping. Ore storage in long-term stockpiles peaks in Year 11 with approximately 19 million tons.

2.4.5.5 Development Rock Production and Storage

Development rock from the three open pits would be sent to five different permanent destinations over the mine life including the TSF embankment and rind fills; the TSF Buttress; the mined-out Yellow Pine open pit; the mined-out Hangar Flats open pit; and the Midnight area within the mined-out West End open pit. In addition to these five areas, other destinations would receive development rock from the three open pits including a temporary ore stockpile base within the West End open pit, a foundation for stockpiling growth medium and recovered seed bank material, a reclamation materials stockpile located on the TSF Buttress, and miscellaneous projects such as road fills and ore stockpile foundations. The development rock production rate would vary throughout the life of the mine because the cut-off grades demarcating ores from development rock would vary due to fluctuating economic conditions. At
individual open pits, the determination between ore and development rock is initially based on the mine 
plan and the delineation of the ore and development rock as determined through production mapping and 
analysis of blast hole cuttings in the grade control program. Approximately 280 million tons of 
development rock from active mining areas would be used to construct the TSF embankment and buttress, 
and placed in the mined-out pits, as described in Table 2.4-9.

After the main portion of the Yellow Pine pit has been mined and mining commences in the northern 
portion of the pit, development rock would be end-dumped into the Yellow Pine pit as backfill. The 
dumped development rock would not be mechanically compacted, except as it nears the final reclaimed 
surface elevation of the backfilled area.

The upper lifts of the backfill would be placed by direct dumping and compaction. The final backfill 
would be covered with a geosynthetic liner and soil/rock cover, and the East Fork SFSR and Stibnite 
Lake would be established across the backfill in a geosynthetic-lined stream/floodplain corridor. The 
inclusion of the lined Stibnite Lake on the Yellow Pine pit backfill would help buffer temperature 
extremes in the East Fork SFSR and replace the fish habitat of the existing Yellow Pine pit lake. The 16-
million-gallon lake feature was designed based on results of lake temperature modeling to reduce diurnal 
temperature fluctuations while increasing average temperatures in effluent stream flow (see also Sections 
4.9.2.2 and 4.9.2.4, Brown and Caldwell 2021i, Rio ASE 2021). Development rock to backfill the Yellow 
Pine pit would be sourced predominantly from the West End pit, with minor quantities originating from 
the Yellow Pine and Hangar Flats pits.

Once mining ceases at the Hangar Flats pit, development rock to backfill the Hangar Flats pit would be 
sourced predominantly from the West End pit. The Midnight pit, a portion of the West End pit in the 
southeast corner of the pit near Midnight Creek, would be backfilled concurrent to mining the West End 
pit, with development rock from the West End pit once mining in the area to be backfilled is completed.

In addition to the permanent development rock storage described above, a temporary DRSF would be 
constructed within the West End pit during road construction and pre-stripping activities. This temporary 
DRSF would contain approximately 2.5 million tons and serve as the base for the West End In-Pit 
stockpile. The purpose of this DRSF is to reduce the need for mixing the smaller development haul truck 
traffic with production haul truck traffic for safety purposes, and to provide a base for stockpiling ore 
encountered during road development and pre-stripping within the West End pit. Since this is a temporary 
DRSF entirely within the footprint of the West End pit, it would be rehandled during regular mine 
operations at the West End pit and relocated to other facilities for permanent development rock storage.

Perpetua has conducted geotechnical investigations supporting the design of the development rock 
backfills.

Surface water and groundwater management for facilities that permanently store development rock are 
discussed in Section 2.4.5.10, Surface Water and Groundwater Management. A Development Rock 
Management Plan, which describes procedures and methods for active management of development rock 
that is produced and stored across the SGP during operations, has been provided (Brown and Caldwell 
2021d).

Source: Perpetua 2021a

\(^1\)The TSF Buttress was formerly referred to as the Hangar Flats Development Rock Storage Facility. To be consistent with the naming convention used for the other backfilled pits, the 2021 MMP uses the term Hangar Flats pit backfill for the backfilled Hangar Flats pit.

\(^2\)Limited amounts of development rock would be used to construct haul roads and pad areas for site facilities. In addition, some development rock may be crushed and screened for use as road surfacing material and/or concrete aggregate. The Development Rock Management Plan (Perpetua 2021c) specifies testing to determine which development rock can be used for these applications.

\(^3\)The source of development rock for TSF construction includes material from the SODA and the Hecla heap leach facility.
2.4.5.6 Spent Ore and Legacy Tailings Removal in Meadow Creek Valley

The Meadow Creek Valley contains legacy materials created from historical mining activities. Legacy materials include development rock, spent ore in the unlined SODA, the Bradley Mill Tailings, and run-of-mine and crushed ore in the historical lined heap leach pads. An Environmental Legacy Management Plan (Perpetua 2021d) describes procedures and methods for active management of legacy materials encountered during construction and mining operations. While the TSF is being built and expanded, Perpetua would remove and reuse as construction material the 7.5 million tons of spent ore within the unlined SODA and other areas (Hecla and Stibnite Mine Inc. leach pads). Physical and chemical testing of the legacy material would determine if the material were suitable for construction uses and determine the final placement of the material. During the first four years or so of ore processing operations, Perpetua would remove and reprocess the three million tons of Bradley tailings underlying the SODA. The legacy tailings would be mixed with water and then pumped to the ore processing facility. The temporary water addition and pumping facility would be an enclosed, heated structure located within the limits of the SODA.

If other legacy materials are encountered during construction they would be removed and hauled off site to an appropriate disposal facility, placed in the TSF, used as pit backfill or construction material, or left in place, depending on testing to determine physical and chemical suitability.

Legacy development rock not used for TSF construction purposes or reprocessed would be placed in pit backfills or used for the TSF Buttress.

2.4.5.7 Ore Processing

During operations, approximately 115 million tons of ore would be mined from the three proposed pits and processed at the mill facilities during the approximately 15-year process facility operation. At full operation, targeted ore production would range from 20,000 to 25,000 tons per day, which would be transported to the processing facility to separate the gold, silver, and antimony from the ore. Additional details on ore processing can be found in section 17 of SGP’s updated feasibility study (M3 2021).

Ore feed for processing would be sourced from either the open pits, Bradley tailings, the SODA, the short-term stockpiles, or long-term stockpiles. Typically, ore would be hauled directly from the pits to the primary crusher whenever the mill is capable of receiving the ore based on grade and metallurgy. If the ore requires short-term stockpiling due to process constraints or haul truck congestion at the primary crusher, it would likely be placed in the short-term stockpile. Ore that is lower value than other ore available at the time of pit mining would be placed in long-term stockpiles.

Ore would be hauled to the crusher, either directly from one of the three open pits or from the ore stockpiles and would be crushed and ground to reduce the size of the rock to separate the gold, silver, and antimony-bearing minerals from the host rock. The ore processing flow sheet is shown on Figure 2.4-9. The ore processing facility and associated support infrastructure are shown on Figure 2.4-2.

The ore processing area would be designed to provide for containment of ore processing materials, chemicals, wastes, and surface runoff. Potentially hazardous chemicals and wastes would be stored within buildings or areas with both primary and secondary containment. Surface runoff within the ore processing
area would be directed to a contact water pond for collection. Any leaks or spills escaping both primary and secondary containment would flow to the contact water pond for collection and would not discharge off site.

The processing would result in production of an antimony mineral concentrate, gold- and silver-rich doré, tailings, and other waste products. Tailings disposal is discussed in Section 2.4.5.1, Tailings Storage Facility.

**Crushing and Grinding**

Mined ore would be hauled to the crusher and typically direct-dumped into the jaw crusher or stockpiled at the uncovered run-of-mine stockpile area near the crusher. Stockpiled ore would be loaded into the crusher dump pocket, based on crusher availability, using a loader. Surface water runoff from the run-of-mine ore stockpile area would be captured and directed to a pond and be used in the ore processing facility (Section 2.4.5.10).

Following crushing, the crushed ore would be transported via conveyor to a dome-shaped, covered stockpile. Dust emission controls would reduce dust from crushing, conveying, and stockpiling. Apron feeders below the crushed ore stockpile would convey the ore to a semi-autogenous grinding mill followed by a ball mill for additional size reduction of the ore. Grinding would occur within an enclosed building to reduce noise levels and facilitate maintenance of the milling equipment. Grinding with process water would reduce the ore to the size of fine sand in a water slurry for further processing.

**On-site Lime Generation**

Ground limestone and lime are needed for pH adjustment in the SGP ore processing plant. Rather than trucking these materials to site from an off-site source, a limestone bed in the West End pit is of suitable quality and quantity to satisfy the life-of-mine SGP requirements for lime. Over the life of the mine, approximately 130,000 to 318,000 tons of limestone would be mined annually, averaging approximately 240,000 tons per year. Approximately 25 to 30 percent of the limestone mined annually would be crushed and run through an on-site lime kiln to produce metallurgical lime powder, with the remainder (70 to 75 percent) would be crushed and stockpiled for direct use as limestone. Both ore and limestone would be temporarily stored at the run-of-mine stockpile area.

The on-site lime generation would require additional equipment, which would be placed within the ore processing area. This equipment would include: limestone crusher and conveyor, propane-fired kiln (200 tons per day output capacity), kiln combustion air system including preheat heat exchanger, propane storage tank plus vaporizer, air compressor, receivers, and dryers for plant air and instrument air at kiln area, roll crusher for kiln product discharge, conveyors for moving feed and product materials, off-gas fume filter for kiln discharge, dust collector kiln feed bin, storage bin for kiln feed material; and storage bin for lime products. The limestone crusher, screens, conveyors, and feed bins would not be enclosed. Dust would be controlled in a similar manner to the ore crushing and conveying process through the use of water sprays and/or bag house dust collectors.
Figure 2.4-9
Overall Process Flow Diagram
Stibnite Gold Project
Stibnite, ID

Data Source: Perpetua 2021
Antimony Flotation

Two flotation circuits would be utilized; one circuit produces an antimony concentrate, and the other produces a gold-rich sulfide concentrate. Ore high in antimony would be processed by the antimony circuit to produce an antimony concentrate (M3 2021). Following grinding, the ground ore slurry would be mixed with lime and small amounts of sodium cyanide or equivalent to inhibit flotation of the gold-bearing minerals (pyrite and arsenopyrite). Lead nitrate or equivalent would be added and then a sulfur- and phosphate-bearing organic chemical. These chemicals make the stibnite mineral particles hydrophobic where the particles then attach to air bubbles and float to the surface in the stibnite flotation tanks. The gold-bearing mineral particles which do not adhere to the bubbles in the stibnite flotation tanks would drop to the bottom of the flotation tanks and be routed to the subsequent gold flotation circuit for further processing. The antimony flotation facility would have interior curbing high enough to contain 110 percent of the volume of the largest tank.

The stibnite-laden bubbles form a froth and would be collected from the top of the stibnite flotation tanks. The stibnite concentrate froth would be subjected to one or two additional flotation steps to further clean the concentrate. The resultant antimony-rich concentrate would be finally thickened and filtered. The final antimony concentrate would be placed in 2-ton supersack containers ready for shipment off site for further refining.

Antimony Concentrate Transport

The antimony concentrate would contain approximately 55 to 60 percent antimony by weight. The remaining balance, 40 to 45 percent by weight, of the concentrate includes sulfur and common minerals with trace amounts of gold, silver, and mercury. As described in the Transportation Management Plan (Perpetua 2021e) for transportation of antimony concentrate, Perpetua would load the sealed 2-ton super sacks containing the concentrate into a shipping container at the processing facility. Perpetua would load the concentrate by forklift and hooked lifting racks to safely move the super sacks, which are equipped with lifting straps, into fully enclosed shipping containers for the full course of their transport from the SGP site to their final destination. The supersacks and shipping container would provide primary and secondary containment for the antimony concentrate (Perpetua 2021e). The concentrate would be trucked via SH 55 to a commercial truck, train, barge, ship loading facility depending on the refinery location. An estimated one to two truckloads of antimony concentrate would be hauled off site each day. It is assumed that the concentrate, when sold, would be shipped to facilities outside of the U.S. for smelting and refining because there are currently no smelters in the U.S. with capacity for refining the antimony concentrate.

Gold and Silver Flotation

Low-antimony mill feed would be processed in the gold flotation circuit only, bypassing the antimony circuit (M3 2021). Gold and silver flotation is a process similar to that described for stibnite flotation, and would be housed in the same building, but using different chemicals to float pyrite and arsenopyrite, the minerals that contain the gold and silver. The flotation building would have interior curbing high enough to contain 110 percent of the volume of the largest tank. The flotation froth, with particles containing gold and silver, would be collected and pumped to the gold concentrate thickener to further separate the gold/silver mineral particles from the process water which would be recycled. The particles from gold
flotation that do not float would become the tailings slurry. The gold and silver concentrations of the tailings would be regularly monitored and, if the concentrations are high enough to warrant further processing, they would be sent to the leaching circuit; otherwise, the tailings would be thickened to recycle additional process water and then routed to the TSF as described below.

**Oxidation and Neutralization**

An autoclave system would be used to oxidize the sulfide minerals comprising the gold and silver concentrate to liberate the gold and silver for subsequent leaching. Before the gold concentrate is pumped into the autoclave, it would be mixed with appropriate amounts of ground limestone to maintain a constant free acid level of approximately 10 grams per liter in the autoclave. This value was established through bench and pilot-scale metallurgical testing to promote the formation of stable, crystalline arsenic compounds in the autoclave. Oxygen would be injected into the autoclave to promote the oxidation reaction, and the temperature in the autoclave would be maintained at approximately 220 degrees Celsius. Water would be injected into the autoclave as needed to control the temperature. After pressure oxidation, the acidic slurry containing gold and silver would be neutralized using slurried lime and other chemicals and cooled in two forced draft cooling towers. The neutralized slurry would then be sent to the leach circuit for recovery of gold and silver from the slurry.

When increasing arsenic levels are observed, the oxidized slurry would be treated with hot arsenic cure (HAC) prior to neutralization. Metallurgical tests showed that this process promotes formation of the stable crystalline form of the arsenic precipitate enhancing environmental stability of arsenic.

The autoclave system would be housed in a steel frame building set on concrete foundations, with interior curbing to provide secondary containment. Air emissions from the pressure oxidation facility would be captured in a series of air pollution controls, and the material collected would be disposed of as a solid waste or a hazardous waste depending on the waste characterization.

**Gold and Silver Leaching and Carbon Adsorption**

The gold and silver leaching component of the recovery process would be regulated by IDEQ under the Cyanidation Rule (Idaho Administrative Procedures Act [IDAPA] 58.01.13) and would be designed and operated consistent with the International Cyanide Management Code for the Manufacture, Transport, and Use of Cyanide in the Production of Gold which is described in Section 3.7.3 (Perpetua 2021a). Gold and silver leaching and carbon adsorption would occur in a steel frame building set on concrete foundations, with secondary containment of 110 percent of the volume of the largest tank and could include audible alarms, interlock systems, and/or sumps, as spill control measures (Initiative for Responsible Mining Assurance 2018).

The leaching to recover gold and silver from the oxidized gold and silver concentrate slurry would occur in large carbon-in-pulp (CIP) tanks which would be fully contained to capture, retain, and recycle process solutions. Sodium cyanide would be added to the tanks containing the neutralized solution to form a gold-silver-cyanide complex and activated carbon would then be added to the tanks to promote the adsorption of the gold-silver-cyanide complex onto the carbon (Figure 2.4-9). The pH of the slurry in the leach circuit would be closely managed at an elevated level to maintain the cyanide in a stable soluble form.
The loaded carbon with gold-silver-cyanide complex attached would then be collected on screens and sent to the carbon stripping circuit. Inside sealed tanks, the carbon with the gold-silver-cyanide complex would be washed with an acid solution to remove impurities, rinsed with fresh water, and stripped of the gold using a hot alkaline elution solution. The resulting gold and silver-bearing elution solution would be piped to the electrowinning and refinery area.

The acid solution used during carbon stripping would be reused until it loses its effectiveness. The solution would be neutralized and sent to the tailings thickener for pumping to the TSF. Air emissions from the leaching facility would be captured in a series of air pollution controls, and the material collected would be disposed of as a solid waste or a hazardous waste depending on characterization of the waste.

**Gold and Silver Electrowinning and Refining**

The gold and silver electrowinning and refinery facility would be a closed-circuit system with 110 percent containment of the largest vessel. The elution solution pumped into electrowinning cells which would electrolytically precipitate the precious metals into a solid sludge that would be removed from the elution solution with a filter. The solid precipitate would then be heated in a retort system to drive off and collect any contained mercury. The gold and silver precipitate from the retort would then be mixed with flux and then placed into an induction furnace and heated. The molten material from the induction furnace, consisting of gold and silver metal and slag, would be poured into molds to cool. The slag would be recycled within the mill circuit and the doré gold/silver bars would be shipped off site to refineries for further processing and refining.

Air emissions from the induction furnace and retort would be treated in a series of emission controls. Mercury metal would be securely stored prior to shipment to a certified hazardous waste disposal facility.

**Tailings Neutralization Circuit**

Cyanide-bearing process slurry from the carbon-in-leach (CIL) circuit would be neutralized within the ore processing plant to less than approximately 10 milligrams per liter weak acid dissociable cyanide before being pumped to the TSF. Residual cyanide in the slurry would be treated using a sodium metabisulfite and air system to oxidize cyanide to form cyanate. After neutralization, tailings would be routed to one or more tailings thickeners, to partially dewater the tailings before they are pumped to the TSF. The process water separated from the thickened tailings slurry would be recycled within the ore processing facility. The neutralized and thickened tailings slurry would be pumped to the TSF.

**Tailings Pipeline Maintenance Pond**

Lined tailings pipeline maintenance ponds would be located at the truck shop and at the ore processing facility, to which tailings slurry from the tailings pipeline between the mill and the TSF or and process water from the tailings reclaim pipeline could drain by gravity during maintenance shutdowns or if there were a leak in either pipeline. The ponds would typically be empty except during maintenance or unforeseen problems with the tailings or reclaim water pipelines, pumping system, or TSF. The ponds are designed to contain the contents of the pipelines and the runoff from the pond and open-trench portions of the lined pipeline corridor from a 100-year, 24-hour storm event plus snowmelt.
### 2.4.5.8 Tailings Storage Facility

The TSF would be located on NFS lands within the Meadow Creek valley (Figure 2.4-2). The TSF, its embankment, and associated water diversions would occupy approximately 423 acres at final buildout with approximately 405 acres of new disturbance. Perpetua has conducted geotechnical and geophysical investigations to support the design of the TSF and associated buttresses. The TSF at the end of operations would be capable of holding approximately 120 million tons of tailings, the operational water pool, and precipitation falling within the TSF and contributing watershed up to the 24-hour Probable Maximum Precipitation event of 11.74 inches of rainfall. Additional details on ore processing can be found in section 18 of SGP’s updated feasibility study (M3 2021).

The TSF would consist of a rockfill embankment, a fully-lined impoundment, and appurtenant water management features. The TSF Buttress located immediately downstream of, and abutting against, the TSF embankment would substantially enhance embankment stability.

Design criteria were established based on the facility size and risk using applicable dam safety and water quality regulations and industry best practice for the TSF embankment on a stand-alone basis; the addition of the buttress substantially increases the safety factor for the design to about double the minimum requirements. The upstream face of the TSF embankment and the Meadow Creek valley where the TSF impoundment would be located would be fully lined to minimize leakage. The TSF would be surrounded by an 8-foot high, chain-link fence designed to keep wildlife, such as deer and elk, from entering the impoundment area. The TSF includes an engineered, rockfill starter embankment. Historical development rock (i.e., waste rock), spent ore from the historical SODA and heap leach areas, and development rock from mine pits would be used for the TSF embankment construction. The TSF Buttress would be built by first constructing a ramp along the north side of the valley to access the crest of the TSF embankment and upper portions of the buttress (Figure 2.4-10). Historical spent ores from the SODA and Hecla heap leach would be placed as bedding on the upstream face of the embankment or impoundment fill prior to placement of the liner to minimize interaction with infiltrating surface water. The starter embankment would be constructed to an elevation of 6,850 feet (or 245 feet above the existing ground surface). The TSF Buttress would then be constructed upwards to further access TSF embankment lifts while the base expands down the valley (eastward) as historical spent ore and legacy tailings are removed from the valley bottom. Engineered fill would be placed against steep slopes within the impoundment to flatten and smooth slopes to facilitate liner placement. This method of construction would allow for controlled material placement across the valley from the ramp north of the valley to the south side. The TSF Buttress would provide additional short- and long-term geotechnical stability. The final embankment height would be 475 feet at a crest elevation of 7,080 feet (Figure 2.4-11).

#### TSF Underdrain System

The TSF would have an underdrain groundwater collection and conveyance system located beneath the liner. Prior to construction, the area would be evaluated for springs and seeps. Evaluations would consist of visually identifying intermittent wet areas (seeps), areas with flowing water (springs), or areas supporting increased plant growth when compared to surrounding areas (see section 18 of M3 2021 for additional detail).

Figure 2.4-11
TSF and TSF Buttress Cross-Sections, Years 4 to 12
Stibnite Gold Project
Stibnite, ID

Date Sources: (Perpetua 2021a)
Groundwater underdrains would be a series of parallel drains with branching laterals, instead of a single valley bottom drain, due to the broad u-shaped nature of the Meadow Creek valley (Figure 2.4-15). Pipes would transition from perforated (able to collect groundwater) to solid-wall (for conveyance only) as they exit their respective collection areas (impoundment and embankment) and flow underneath the buttress to the outlet. Underdrain flows would be collected in a sump downstream of the toe of the buttress, monitored for water quality, then either discharged to surface water through a permitted Idaho Pollution Discharge Elimination System (IPDES) discharge, or pumped to the ore processing facility or a contact water pond for either treatment and discharge or use as makeup water for the mill process. The TSF liner system would then be installed in the TSF impoundment area over the underdrain system.

Underdrains would be installed beneath the TSF Buttress to ensure that groundwater does not saturate the base of that fill and potentially lead to water quality impacts or geotechnical instability; however, little if any flow is expected in the buttress underdrains owing to lower observed groundwater levels beneath the buttress. Underdrain collection sumps and downgradient monitoring wells would be used for TSF leak detection.

**TSF Liner System**

Due to water quality regulations and the presence of dissolved metals (chiefly arsenic and antimony, with trace mercury) and residual cyanide in the tailings pore water and supernatant pool, the TSF impoundment (including the upstream embankment face) would be composite-lined with geosynthetic materials to prevent seepage of process water or transport of tailings out of the facility. A network of geosynthetic drains would be placed above portions of the geomembrane liner to reduce hydraulic head on the liner and excess pore pressure in the overlying tailings. The drains would report to a sump near the upstream embankment toe, and the water would be pumped out to the pool or reclaim system for reuse (M3 2021).

A composite liner consisting of a 60-mil, single-sided, textured, linear low-density polyethylene liner over a geosynthetic clay liner (GCL) would be employed to contain the tailings. Before placement of the liner within the TSF, the subgrade would be re-worked and compacted, or a minimum of 12 inches of buffer/liner bedding fill would be placed. Geosynthetic overliner drains would be placed above portions of the liner to reduce hydraulic head on the liner and pore pressure in the overlying tailings solids during operations. The drains would direct water that migrates through the tailings to a sump near the upstream toe of the embankment, and the water would then be pumped out to the tailings pool within the impoundment or the reclaim system for reuse in the mill.

Facilities that use cyanide in their mineral extraction process are required to obtain a permit from the Idaho Department of Environmental Quality (IDEQ) and follow the Rules for Ore Processing by Cyanidation (IDAPA 50.01.13). The IDEQ entered into rulemaking on the existing regulations to change the regulatory requirements from prescriptive requirements to performance-based requirements. A temporary Rule went into effect in October 2020, and the final rule was approved by the legislature in 2021. The liner system proposed for the SGP meets the requirements of the rule under which the Project’s Cyanidation permit is expected to be issued.
**TSF Management Support Facilities**

Light vehicle roads and haul roads would provide access between the ore processing facility and the TSF, and the tailings delivery and reclaim water return pipelines would parallel the haul road. Secondary containment in the event of a pipeline break would consist of a geosynthetic wrap or an open geosynthetic lined trench. Further, the pipeline corridor would drain to one of two pipeline maintenance ponds – one at the truck shop and one at the ore processing facility. Electrically-powered pumps would be located at the TSF to pump tailings to the TSF and reclaim pumps would be located at the TSF to return water to the ore processing facility for reuse.

**TSF Water Management**

Thickened tailings slurry would be pumped to the TSF (see section 18 of M3 2021 for additional details). The TSF would be designed and operated as a closed-circuit, zero-discharge facility meaning no tailings water would be discharged to the surface water or groundwater except in compliance with applicable permits and regulations. As the tailings consolidate, water collected in or falling on the surface of the TSF would form the supernatant pool on top of the tailings and be reclaimed for use in ore processing. Cyanide levels in the TSF reclaim water would be monitored throughout operations to ensure they remain in compliance with issued approvals and permits.

### 2.4.5.9 Mine Support Infrastructure

SGP infrastructure to support surface mining and ore processing operations would include the following:

- A one-story mine administration building that would be sided or painted and roofed in neutral colors.

- A maintenance workshop which would store materials and supplies as discussed in Section 2.4.5.14, Materials, Supplies, Chemical Reagents, and Wastes.

- A truck wash facility which would include an oil/water separation system and water treatment facilities to enable recycling of the wash water.

- A worker housing facility ([Figure 2.4-12](#)), which would be constructed on NFS lands adjacent to Thunder Mountain Road (FR 50375) and would accommodate up to 500 people. This facility would include dormitories, food service, and recreation facilities, along with the supporting infrastructure of power, water supply, and wastewater treatment plant. The SGP main gate and security building would be co-located with the worker housing facility.

- Haul roads to transport ore, development rock, and reclamation materials from mining or storage areas, and to transport vehicles to the maintenance workshop. A typical haul road travelway would be approximately 87 feet wide (81.1 feet of running surface and 5 feet of safety berm width). The haul roads would be built and maintained for year-round access and would be surfaced with gravel materials. Road maintenance activities would be conducted to manage fugitive dust emissions and maintain stormwater management features.
Figure 2.4-12
Worker Housing Facility
Stibnite Gold Project
Stibnite, ID

Data Sources: Perpetua
• Culverts would be installed where haul roads cross drainages or to direct stormwater to collection and retention structures. Culvert inlets and outlets would be lined with rock riprap, or equivalent, as needed to prevent erosion and protect water quality. Crossings of known fish-bearing streams would be constructed to support fish passage, with appropriately designed and constructed culverts or bridges.

• Service roads and paths that would provide an internal access system for employees and visitors to the site. The service roads would typically be 12 to 15 feet wide; some would be graveled or covered with rock aggregate, while others would be two-track roads. There would be no planned public use of the SGP service roads or trails. The path system would enable SGP pedestrian traffic to move safely throughout the SGP operating area. Service roads and paths would be located within the overall disturbance area defined for the SGP and existing roads would be used to the extent possible.

• Employee and visitor parking that would be maintained during construction and operations. During construction, the gravel parking areas would be located at the new worker housing facility, near the contractor/construction laydown areas, and at the Scout Portal. As operations are initiated, gravel parking areas would be maintained for buses, vans, and other miscellaneous vehicles for employees, contractors, vendors, and visitors at the new worker housing facility, at the shop area, and near the mine administration office.

2.4.5.10 Surface Water and Groundwater Management

Surface Water Management

To manage surface water at the SGP, existing streams that run through areas proposed for mining related disturbance would be diverted. Temporary diversions would be used within the SGP to keep non-contact water separated from contact water. Contact water is water that flows into or through disturbed areas and mining facilities and could have the potential to pick up increased levels of sediment, metals, and other possible contaminants which cannot be discharged into surface water and groundwater without proper treatment. Non-contact water is meteoric water that does not contact disturbed areas or mining facilities.

Stream Diversions around Mining Features

Existing streams would be temporarily diverted around SGP facilities, within constructed surface water channels. Diversion channel segments constructed in erodible materials would be lined with riprap to prevent erosion. Rock-cut channels would be constructed on steep slopes and in areas with shallow or at-surface bedrock, would have low erosion potential, and not require riprap lining. Certain channel segments constructed over fill or excavated in permeable materials would be lined with a geosynthetic liner to prevent seepage. A geotextile and/or transition layer of sand/gravel followed by riprap would be placed over the liner for erosion protection. Certain diversion sections would be piped as dictated by terrain or the need to limit warming of water.

During mine operations, summer low flows in perennial diversion channels around the TSF impoundment and buttress (Meadow Creek), Yellow Pine pit (Hennessy Creek), and West End pit (West End Creek) would be piped underground as an environmental design feature to maintain cold stream temperatures.
Eight- to 12-inch-diameter pipes, sized to convey August baseflow, would be installed under the diversion channels in the riprap channel lining or under the adjacent access road to carry low flows. Stream flow would enter pipes through inlets at the same locations stream and tributary inflows would be diverted into the constructed channel. Some diversions, such as portions of Hennessy and West End Creeks, and the East Fork SFSR tunnel, would be entirely underground, in which case conduits would be larger and sized for high flows.

**East Fork SFSR Temporary Diversion Tunnel**

Currently, the East Fork SFSR flows into and through the Yellow Pine pit lake. The cascade at the inflow to the pit lake currently blocks upstream fish passage. A tunnel would be built to direct the East Fork SFSR around the west side of Yellow Pine pit to allow mining in the pit and fish passage during construction and operations (Figure 2.4-13). The tunnel would be approximately 0.9 mile long and 15 feet high by 15 feet wide. The tunnel would include a fishway stream channel designed to provide for upstream and downstream passage of migratory and anadromous salmonid fish.

The tunnel would be designed so that fish could swim through its entire length in both directions (Brown and Caldwell, McMillen Jacobs and BioAnalysts 2021a). To encourage fish passage, low-energy lighting would be installed in the tunnel and set on timers to simulate daylight. A trash rack would be constructed near the upstream entrance to the tunnel to prevent large wood, boulders, and other debris from entering the tunnel, and would be cleaned periodically. The spaces between the trash rack bars would be sized to allow passage of adult Chinook salmon. A surface water supply intake with fish screens would be installed upstream of the trash rack at a control weir to divert water from the East Fork SFSR for ore processing makeup when necessary.

A parallel roadway would be constructed in the tunnel to allow equipment and personnel access for monitoring, inspection, and maintenance. The accessway would function as a floodway for high flows, greater than the normal flow range within the fishway.

The tunnel fishway would incorporate concrete weirs, designed to produce hydraulic conditions that could be successfully navigated by fish (McMillen Jacobs 2018). The south portal (upstream end) of the tunnel would include a sediment collection and drop out area, a resting pool, trash rack, flow control weir, and picket panels. The north portal, located at the downstream end of the tunnel, would include an orientation pool for downstream migrating juvenile fish with an adult exclusion barrier to reduce potential predation, a separate adult fish holding/resting pool, rock weirs and a transition zone. Specific details on the north and south portals, plus the overall design, function, operation, and maintenance of the diversion tunnel are thoroughly described in the Fishway Operations and Management Plan (Brown and Caldwell, McMillen Jacobs, and BioAnalysts 2021a).

**Midnight Creek**

Midnight Creek is a first order, perennial, non-fish-bearing stream. The Midnight Creek stream diversion would reroute approximately 0.3 mile of the lower portion of Midnight Creek to the south, away from where it currently enters the Yellow Pine pit lake. The rerouted creek would be piped under haul roads so that it would enter the East Fork SFSR upstream of the proposed tunnel portal (Figure 2.4-14). The Midnight Creek diversion would manage flows in Midnight Creek during Yellow Pine pit operations and
backfill activities until the newly developed East Fork SFSR alignment over the backfilled pit is complete and stabilized as described in Section 2.4.7.4.

**Hennessy Creek**

Hennessy Creek is a first order, perennial, non-fish-bearing stream. Hennessy Creek would be diverted south of Yellow Pine pit in a pipe along the public access road at the western edge of the pit (Figure 2.4-13). The diversion would include an impounding structure, overflow weir, and diversion cleanout basin. Diverted flows would be routed to Fiddle Creek downstream of the existing Stibnite Road culvert crossing, ultimately placing Hennessy Creek flows into the East Fork SFSR upstream of the south tunnel portal and disconnecting flow from the current unlined ditch passing alongside the Northwest Bradley dumps. Overflow, if any, would follow the existing stream channel into the Yellow Pine pit.

**Fiddle Creek**

Fiddle Creek is a second order, perennial, fish-bearing stream. Fiddle Creek would not be diverted. Rather, small stormwater diversions would route hillslope runoff around the Fiddle GMS and a culvert would route Fiddle Creek under the GMS, GMS access road, and public access road.

**West End Creek**

West End Creek is a first order, non-perennial, non-fish-bearing stream. The approximately 1.5-mile-long West End Creek stream diversion would reroute West End Creek around the north side of the legacy West End DRSF and cross the upper benches of the West End pit (Figure 2.4-14). The diversion would consist of a lined channel along the upper legacy DRSF, and a pipe in the segments along a steep hillside above the West End pit, within the pit, and along the steep hillside alongside the lower legacy DRSF down to the outlet at the existing stream channel. The lined channel portion would be designed to convey flows from a minimum 25-year storm event plus 2 feet of freeboard.

**Garnet Creek**

Garnet Creek is a perennial, first order, non-fish-bearing stream. During construction, Garnet Creek would be re-routed downstream of the ore processing facility to a relocated confluence with the East Fork SFSR (Figure 2.4-14). Above the early restoration reach, Garnet Creek would be routed along the upper processing plant site access road in a riprap channel, then cross under the ore processing facility roads in culverts, with environmental design features to reduce sediment loading to the stream, and to protect water quality. At closure, this segment of Garnet Creek would be restored, along with created wetlands at the plant site.

**Meadow Creek**

Meadow Creek is a perennial, third order, fish-bearing stream. Approximately 2 miles of Meadow Creek would be diverted around the south side of the TSF and TSF Buttress. The diversion would direct flows back into the existing SODA diversion upstream of the Hangar Flats pit (Figure 2.4-15). The new diversion would consist of a rock-cut channel in segments along the steep hillsides above the TSF and buttress, and an excavated channel in alluvium across tributary valley segments. Channel segments
excavated in erodible or permeable materials would be lined with rock riprap and/or geosynthetic liner to prevent erosion and to minimize seepage where needed. The Meadow Creek diversion channel around the TSF and TSF Buttress would be designed to convey flows from a minimum 100-year storm event with 1 foot of freeboard.

The stream also would be diverted around the Hangar Flats pit. The Meadow Creek channel would be moved away from the pit to the south/southeast and reconstructed as a sinuous channel and floodplain to allow potential for spawning habitat and establishment of riparian habitat within the floodplain. A liner would be installed under the stream/floodplain corridor to minimize water seepage into the Hangar Flats pit or the pit dewatering well system, and to avoid potential pit wall instability or loss of stream habitat as a result of stream dewatering. The Meadow Creek diversion channel/floodplain corridor around the Hangar Flats pit would be designed to convey flows from a minimum 100-year storm event with 3 feet of freeboard; as a natural channel design, the stream channel itself would be designed for bankfull flows (1.5-year recurrence). This diversion would be permanent and incorporates design aspects to resemble natural channels not applied to temporary diversions of the other creeks. This permanent design accounts for channel migration, flooding, riparian development, and biological habitat.

**Blowout Creek**

Blowout Creek is a first order, perennial, fish-bearing stream outside the Project operational footprint. Blowout Creek (aka East Fork Meadow Creek [EFMC]) was impacted by the failure of a water storage dam in 1965 creating a steep actively eroding channel that conveys Blowout Creek. Perpetua proposes to stabilize and repair the failed area of Blowout Creek in the actively eroding chute and raise groundwater levels in the meadow upstream of the former dam site to restore wetland hydrology. A structure to control the grade of the creek would raise groundwater levels in the meadow and a coarse rock drain would address ongoing erosion of the channel side slopes that currently deliver sediment directly to the creek, while facilitating construction of a permanent surface channel. This would be an SGP environmental design feature and restoration effort, as the Blowout Creek chute and upper meadow are unrelated to and unaffected by the proposed mine features. The lower portion of the Blowout Creek alluvial fan would be an important borrow area for this and other restoration projects and is included in Project disturbance.

During construction and early mining, Perpetua would construct grade control and water retention features near the old reservoir water retention dam location to elevate the groundwater level and stream water surface sufficiently to restore wetland hydrology in the surrounding meadow. The retention structure would impound portions of the meadow channel, which would fill with sediment over time.

A coarse rock drain would be constructed within the chute downstream of the failed dam site to isolate the flow of Blowout Creek from the actively eroding chute side slopes and to prevent further erosion of the gully bottom, facilitating subsequent restoration of a surface channel on top of the drain. The rock drain would also provide area for the collection and retention of side-slope erosion material rather than allowing that material to potentially contribute sediment to Blowout Creek. As the rock drain fills with sediment, it would become closed off from the stream channel and flow would revert to the designed surface channel.

2021 MMP Water Management Plan - Meadow Creek Stibnite Gold Project Stibnite, ID

Data Sources: (Perpetua 2021a)
The existing alluvial fan in lower Blowout Creek, located adjacent to Meadow Creek, would be removed, mostly during mine operations for borrow materials, and the area reclaimed. A surface diversion would be constructed at the margin of the lower alluvial fan to facilitate borrow excavation, and this stream reach subsequently restored.

Non-Contact Stormwater Diversions

Non-contact stormwater is meteoric water (i.e., precipitation) that does not contact tailings, open pits, the TSF, TSF Buttress, spent heap leached ore, and tailings from past mine operations, or any other mining related surfaces. Stormwater runoff from undisturbed areas upslope of mine features in the major drainages would be captured in stream diversion channels described above or in other channels that would direct runoff away from mine disturbed areas. Smaller-scale diversion channels or earthen berms would be used, where necessary, to divert stormwater around other mine infrastructure. Non-contact water would be managed with features to reduce erosion and sediment delivery to streams. Where sedimentation is a concern, non-contact water stormwater diversions would be routed to sediment catch basins where the water can evaporate, infiltrate, or discharge into the stream system after settling. Energy dissipation structures would be installed at the non-contact surface outfalls as needed.

Contact Water

Water that contacts mining disturbances and has the potential to impact water quality is termed contact water. Contact water includes, but is not limited to, runoff from mine facilities such as the TSF, TSF Buttress, stockpiles, mine pits, haul roads constructed of development rock, toe seepage of precipitation infiltrating through the stockpiles, and underground exploration water. Collection of contact water would begin during the first year of on-site construction and would continue throughout operations and the closure and reclamation phases. Contact water would be captured in channels and sumps and routed to the ore processing facility, contact water storage ponds, water treatment plant, or enhanced evaporation systems. In unusually high runoff periods collected water may be allowed to remain in the pits or the TSF temporarily, excess contact water from outside of the pits may be routed to mine pits for temporary storage. Contact water storage ponds would be lined to minimize leakage. Water in the contact water storage ponds could be pumped to the mill for use, treated and discharged in accordance with applicable requirements, or evaporated. Contact water in the mine pits would be directed to in-pit sumps in the lowest part of the pit and piped to the mill for use, to other contact water storage ponds, to water treatment or evaporation, or into trucks for spraying for dust control within open pits and on stockpiles or TSF Buttress. Any contact water beneficially used in the ore processing or for dust control or stored for more than 24 hours then treated and discharged would require water rights permitting through the IDWR prior to use.

Contact water which exceeds regulatory discharge standards set by IDEQ and that cannot be used during operations would be disposed through a variety of methods including forced evaporation using sprayers located within the TSF or other managed areas or treated and discharged. Water would be treated to meet IPDES permit limits and treated water would then be discharged through IPDES permitted outfalls to the East Fork SFSR or Meadow Creek.

Runoff from haul roads and access roads outside of pits, ore stockpiles, or development rock storage areas may be of sufficiently good quality to be eligible for coverage under the Multi-Sector General Permit
(MSGP) for Stormwater Associated with Industrial Activities. Eligibility would depend upon the materials used for road construction and would be determined through coordination with IDEQ with oversight by EPA. Runoff covered under the MSGP would be managed with a variety of environmental design features and conventional stormwater control measures to ensure the protection of surface water quality.

Surface Water Outfalls

The specific number and exact locations of outfalls would be determined via IPDES permitting through IDEQ. Approximate locations of the anticipated outfalls described below are shown on Figure 2.4-14 and Figure 2.4-15. All outfalls would be required to meet water quality limits for specific constituents, and some outfalls may have discharge volume limits where the permit specifies a loading limit. Not all outfalls would necessarily be active or be permitted in the same permit cycle.

Two IPDES surface water outfalls would be used to discharge treated contact water from active mine pits, the TSF Buttress, pit dewatering, legacy mine materials disturbed by new mining activities, and the plant site and truck shop. One outfall located near the plant site would discharge to the East Fork SFSR. A second outfall would discharge to Meadow Creek upstream of Blowout Creek to augment streamflow during pit dewatering.

Water from the TSF and TSF Buttress underdrains may be discharged from two outfalls shown on Figure 2.4-15, depending on whether IPDES discharge limits are met without treatment of the underdrain water (otherwise, underdrain water would be routed to the plant site for use in processing, to the water treatment plant, or back to the TSF). Discharges from these two outfalls are expected to have a strong seasonal component, with some parts of the year seeing reduced flows, or even no discharge, as contact water is used for ore processing or other mine uses.

An outfall would be permitted on upper East Fork SFSR for the sanitary wastewater treatment facility at the worker housing facility. That outfall would be active through the operations period and during mine closure until the facility is decommissioned.

An additional outfall is expected to be permitted in a future IPDES permit renewal for closure and post-closure discharge of treated TSF process water. That outfall would be on Meadow Creek upstream of Blowout Creek near the TSF Buttress.

Additional permitted outfalls may be necessary during a portion of the operations period for contact water storage pond spillways that could discharge to surface water – although discharge would be very rare or non-existent, only occurring in the event of excessive precipitation or snowmelt. The need for additional outfalls associated with pond spillways and their location would be determined with IDEQ.

Each outfall would be permitted through IDEQ and would be required to be monitored, meet discharge limits, and regulate the rate of discharge.

Draining the Yellow Pine Pit Lake

Draining of the existing Yellow Pine pit lake would be initiated during construction. When the East Fork SFSR tunnel diversion is ready, stream flows would start being diverted into the tunnel during a period of
low flow, most likely in the warmer months, and concurrent with salvaging fish from the pit lake and diverted sections of the East Fork SFSR. As the East Fork SFSR water is diverted into the tunnel, the decreased East Fork SFSR flow into the pit lake would be expected to cause some fish to out-migrate, thereby lessening the number of fish requiring salvage and creating better conditions for salvaging fish.

Once fish salvage has occurred in the East Fork SFSR from the tunnel diversion downstream to the pit lake and most of the East Fork SFSR flow is being diverted into the tunnel, fish salvage in the lake would commence and take approximately one week to complete. The pit lake would drain naturally down to the elevation of the outlet of the lake, where the existing rock sill would control the water level, though some leakage and slow lowering via groundwater outflows may occur beyond that level. No erosion or downcutting of the outlet rock sill would be expected because it has endured the full range of East Fork SFSR flows over decades and both inflow and outflow rates would be minimal during draining due to the river flow being diverted into the tunnel. The drain-down process would naturally convey lake water downstream to the East Fork SFSR.

After the natural drain down, water remaining in the pit lake or entering the pit from groundwater seepage or local stormwater runoff from pre-stripping operations on the highwalls above the pit lake would be managed as mine-impacted water. The water pumped from the pit lake would be used for construction purposes, transferred to the TSF (after it is lined and available) for future use in ore processing, or treated to meet permit limits before being discharged downstream in the East Fork SFSR via an IPDES permitted outfall.

Sediment remaining in the pit lake bottom would be removed beginning near the end of the final year of construction. Approximately 80 vertical feet of sediment lies on the pit bottom, and the pit walls are too steep to operate equipment without a ramp. Therefore, removal may be staged to coincide with successively lower benches as the pit is mined, and therefore may extend into the first year of operations. During this time, the pit would be used seasonally to capture and store contact water from the adjacent pit walls, and this water would be used or managed as stated above.

The sediment would be removed using an excavator or similar equipment and loaded into trucks and delivered to the TSF. Slurry/dredging methods are not anticipated but would be considered as part of adaptive management if the sediments are too wet to load and/or blend. The truck beds would have flashboards to minimize water leakage from the low-strength, saturated sediments. The loading area would drain back into the former pit lake, preventing off-site discharge of bleed water during loading. If necessary, wet material would be blended with loose dry material (e.g., development rock) from elsewhere on site to enable better loading, transport, and ultimate stability at the destination.

**Groundwater Management**

Groundwater would require management to allow mining in the pits and to direct seeps and springs from beneath mine facilities. Groundwater also would provide a portion of the water supply for the SGP. Water supply aspects of the mine operations are described in the Water Use and Water Balance subsection below. Any groundwater used within the SGP would require permitting through IDWR prior to use. Depending on final use or disposal of groundwater, wells drilled on the site could be permitted as domestic use, industrial use, or dewatering wells.
Pit Dewatering

Lowering the water table in and surrounding the Yellow Pine, Hangar Flats, and West End pits during operations would increase pit wall stability and provide dry working conditions in the pit bottoms. Development of the Yellow Pine and Hangar Flats pits would require partial dewatering of the alluvium of portions of the East Fork SFSR and Meadow Creek valleys, respectively, to limit groundwater inflow to the pits and maintain stability of the pit slopes. Once the West End pit is mined below the level of West End Creek, the West End pit also would require dewatering.

Dewatering would be accomplished by drilling a series of alluvial and deeper bedrock wells near the pit perimeters to intercept and pump groundwater before the water reaches each pit. Alluvial groundwater at the Yellow Pine and Hangar Flats pits would be managed using a series of vertical wells (Figures 2.4-14 and 2.4-15). The West End pit is primarily in bedrock with only a thin layer of alluvium in the vicinity of the pit and no alluvial dewatering is planned for that pit. Pumps would be installed in each well and would run as necessary to draw down the groundwater and facilitate mining and backfilling operations. Horizontal drain holes in pit walls may also be considered for depressurizing remnant high pore pressure areas.

Groundwater pumped from pit dewatering would be considered to be contact water and would be managed through forced evaporation or active water treatment when the volume of pumped water exceeds the ore processing facility demand. Treated water would be discharged to either of two IPDES-permitted outfalls, either Meadow Creek or the outfall on the East Fork SFSR near the water treatment plant, depending on the need for streamflow support in Meadow Creek.

The pit dewatering wells would be permitted as industrial wells in conjunction with a water right application through IDWR.

Groundwater not captured by the pit dewatering, and entering the pits as highwall seepage, would be directed to an in-pit sump in the lowest part of the pit where it would combine with stormwater and snowmelt runoff (i.e., contact water) from precipitation falling within the pit. The water would be used for dust control within the pits, and as needed, pumped to the ore processing facility for use as makeup water. In-pit water that cannot be used would be disposed of through forced evaporation or routed to the water treatment plant then discharged to the East Fork SFSR or Meadow Creek via IPDES permitted surface outfalls.

Water Use and Water Balance

The water balance is an accounting of inflows, outflows, and storage for various components of the mining and ore processing system. Actual volumes for water balance inputs and outputs could vary seasonally and annually from the volumes estimated. A water balance flow diagram for the mining and ore processing operations phase is provided in Figure 2.4-16 with components of the water balance described below.
Figure 2.4-16
2021 MMP Water Balance
Flow Diagram (Operations)

Stibnite Gold Project
Stibnite, ID
Data Sources: Perpetua 2021a
Water Use and Supply

Sources of water are required for ore processing, surface and underground exploration, dust control, and potable use. Water for industrial and mining uses would be supplied from water pumped from the dewatering wells located around the Hangar Flats, Yellow Pine, and West End pits; industrial water supply wells; contact water storage ponds; a surface water supply intake on the East Fork SFSR; and process water recycled within the ore processing and tailings circuit. Dedicated wells would provide potable water for worker consumption and sanitary use. Projected water use for the SGP is described in Table 2.4-10.

Source: Perpetua 2021a  
gpm – gallons per minute

As shown in Table 2.4-10, ore processing facility operations would represent approximately 97 percent of water use associated with the SGP. A separate wellfield of up to four wells would be developed in the East Fork SFSR drainage adjacent to the worker housing facility to provide potable water for the housing facility. The use of water from pit dewatering, contact water from precipitation runoff, surface water, and development of separate wellfields for supplemental industrial water and potable water at the worker housing facility would require permitting through the IDWR as new water rights or transfer of the place of use for one of Perpetua’s existing water rights. Perpetua has submitted an application to IDWR for a total diversion of up to 9.6 cfs (4,308 gpm) for use by the SGP.

Water for Ore Processing

Ore processing is the primary driver for water use. Water sources for ore processing include water from pit dewatering and water supply wells, contact water, East Fork SFSR surface water intake, and water recycled from the TSF. Outflows from ore processing include tailings slurry conveyed to the TSF and evaporative losses from various process components.

The majority of the water needed for ore processing would be recycled (reclaimed) from the TSF. Reclaim water would be pumped from the supernatant water pool at the TSF to the reclaim water tank at the ore processing facility. Makeup water would be supplied from pit dewatering in wells located around the Hangar Flats, Yellow Pine, and West End pits; water supply wells; contact water; and surface water intake in the East Fork SFSR. Water would be pumped from the pit dewatering wells to freshwater tanks.
near the ore processing facility site. These tank facilities also could supply water for exploration drilling, development drilling, in-pit road dust control, and emergency fire suppression.

The freshwater tanks could store approximately 360,000 gallons of water; 240,000 would be available for process uses, and the remaining 120,000 gallons would be maintained for fire suppression only.

**Water at the TSF**

Inflows to the TSF include tailings slurry and precipitation. The TSF would store tailings solids, water entrained with the tailings, and free water atop the tailings (supernatant pool). Stormwater falling directly on the TSF and water from the supernatant pool, that forms as the tailings consolidate, would be stored in the TSF and reclaimed for ore processing. Water infiltrating to the base of the TSF would be captured by the liner overdrains, enter a sump, and be pumped back to the supernatant pond. The volume of available reclaim water would be influenced by the ore processing volumes, precipitation, and evaporation. The reclaim water would be pumped from the TSF to the reclaim water tank located at the ore processing facility. During periods of site-wide water excess, reclaim can be curtailed and contact water could be used directly in ore processing to facilitate emptying the contact water ponds, while retaining water in the TSF for use in an upcoming dry season. Local stormwater and snowmelt runoff and the existing Meadow Creek would be routed around the TSF.

**Water for Potable Use**

Potable water would be needed for worker consumption and sanitary use. Groundwater would be the primary source of water for potable use at the SGP. An existing well located near the exploration camp in the East Fork SFSR drainage would be used to supply an independent water circuit, along with a separate wellfield in the East Fork SFSR drainage adjacent to the worker housing facility. Wells also would be drilled for potable and industrial or commercial water uses at the Burntlog Maintenance Facility and the SGLF. Perpetua has applied to IDWR for water rights for these wells.

**Water Treatment**

The project’s water treatment requirements, objectives and methods are described in detail in the Stibnite Gold Project Water Management Plan (Brown and Caldwell 2021b) and summarized in this section. Three water types would require treatment over the life of the SGP: contact water from mine facilities, which includes dewatering water (construction through closure); process water from the TSF (closure); and sanitary wastewater (construction through early closure). During operations, treating and releasing contact water would generally be limited to periods when a significant amount of dewatering water is being produced, or seasonally in wet years. Outside of that time, much of the collected contact water could be put to beneficial use in the mill. Any groundwater or contact water put to beneficial use within the SGP mine area would require permitting through IDWR prior to use. During construction and at closure, absent a water demand for ore processing, less contact water would be consumed and proportionally more would be disposed of through evaporation or treatment and discharge. From construction through early closure, the camp and offices would produce sanitary wastewater needing treatment. Additional water treatment that could be required during post-closure is discussed in Section 2.4.7.13, Post-Closure Water Treatment. Permit discharge limits would be developed according to IDEQ and CWA requirements and the limits would be established by the IPDES permit issued by the IDEQ.
The sources proposed for operational water treatment by Perpetua include:

- Contact water from dewatering of the Yellow Pine, Hangar Flats, and West End pits;
- Stormwater runoff (including snowmelt) from the pits, TSF Buttress, Bradley tailings, SODA, Hecla heap leach, run-of-mine ore stockpile area, truck shop, and ore processing facility;
- Toe seepage from the TSF Buttress and long-term ore stockpiles; and
- Sanitary wastewater from the worker housing facility, truck shop, ore processing facility, and administrative buildings.

The conceptual water treatment system during operations would need to adhere to stringent surface water quality standards for regulated constituents, most notably arsenic and antimony. Thus, coupled with the timing of water treatment needs with respect to the mining sequence and dewatering excess, treatment methods and capacity would be phased. During construction and early in operations, a modular, mobile, two-stage iron coprecipitation system would be utilized. Early in operations, this system would be replaced by a two-stage iron coprecipitation system located near the ore processing facility. Residuals (sludge) from the water treatment during construction would be stored in a small impoundment in the TSF footprint. During operations and closure, the residuals would be stored in the TSF. Due to contact water runoff seasonality, reuse, and equalization storage (i.e., ponds), average treatment rates are often significantly less than nominal treatment capacity, except during the Hangar Flats pit dewatering when a substantial proportion of treated water would be from relatively constant dewatering flows.

This is met with a staged water treatment strategy. The construction time period is paired with 300 gpm of peak capacity from package iron coprecipitation plants. The first three years of operations would require 1,000 gpm of total treatment capacity, using an iron coprecipitation plant that would remain until closure. During peak simultaneous dewatering of the Yellow Pine pit and the Hangar Flats pit, an additional 1,000 gpm of modular water treatment capacity would be brought online for approximately three years, then treatment capacity would be scaled back to 1,000 gpm for the remainder of operations and early closure.

At closure, the closure water treatment plant would be constructed to accommodate treatment of water from the TSF which would include iron coprecipitation and the application of reverse osmosis membrane treatment. After mine closure and final reclamation of the TSF Buttress and pit backfill surfaces, contact water treatment would no longer be required; but process water treatment for the TSF (Section 2.4.7.13) would continue longer, through approximately year 40. The closure treatment plant would be located on private land at the TSF Buttress as the TSF would ultimately be the only remaining water source requiring treatment.

Enhanced evaporation, using snowmaker style misters located over the lined TSF, collection ponds, and/or pits, would supplement the treatment system, in particular to prevent surplus process water accumulation in the TSF and eliminate contact water inventory, if necessary, when environmental conditions are conducive to evaporation.
2.4.5.11 **Sanitary Waste Handling Facilities**

Sanitary waste handling facilities would be present at SGP facilities and would be constructed and operated in accordance with Valley County, IDEQ, and Idaho Department of Health and Human Services standards. Sanitary wastewater would be treated using membrane bioreactor (MBR) or similar technology. Early in construction, the currently-permitted MBR plant at the existing exploration camp would be used, and treated effluent reused for flushing toilets and urinals (as allowed by Perpetua’s existing Reuse Permit M-228-02) or discharged to the existing drain field, while the worker housing facility and its associated treatment plant is under construction. During operations and closure, sanitary wastewater from the worker housing facility, ore processing facility, and administration buildings would be treated at a new MBR or similar plant and discharged to the East Fork SFSR via a permitted IDPES outfall. Vaults or portable toilets would be used at off-site facilities and remote locations on site (TSF, pits, maintenance facility etc.), and serviced as needed using vacuum trucks. Treatment residuals would be hauled off site to a permitted sanitary landfill. Vault/portable toilet wastewater would be hauled to the on-site sanitary wastewater treatment plant for treatment.

2.4.5.12 **On-site Composting Facilities and Solid Waste Collection and Disposal**

On-site composting facilities would be permitted by IDEQ with oversight by the local Health District. Small scale composting associated with organic materials generated at the worker housing facility may be incorporated within the centralized GMS in the Fiddle Valley. These composting facilities would be fenced. Any larger composting facilities deemed necessary to support growth media quality or quantity improvements would be located off site.

All construction and demolition waste generated at the SGP would be hauled off site for disposal at a permitted landfill; a landfill would not be constructed or maintained at the SGP. Solid waste from the worker housing facility, shops, and other work areas that cannot be composted or recycled would be collected in wildlife-resistant receptacles and hauled off site for disposal in a municipal waste landfill.

Material that meets the classification of a “hazardous waste” would be collected and stored, per the SGP Waste Management Plan at specially designed and operated secured satellite collection sites and a main storage site prior to shipment off-site to a Resource Conservation and Recovery Act (RCRA) certified hazardous waste disposal facility.

2.4.5.13 **Mine Site Borrow Sources**

Various types of earth and rock material would be used from borrow sources for construction, maintenance, closure, and reclamation activities. Most of these materials can be sourced at the SGP from existing development rock dumps, legacy spent heap leach ore, and from development rock removed as part of proposed surface mining and underground exploration activities. These materials would be subject to physical and chemical testing to determine suitability for use.
Native earth materials would be required for some applications. Specific areas within the SGP that have large quantities of high quality native alluvial and glacial granular borrow materials for use include:

- The alluvial and glacial soils in the Meadow Creek valley floor within the footprint of the TSF, TSF Buttress, Hangar Flats pit, and Yellow Pine pit;
- Sand, gravel, and cobbles in the lower Blowout Creek alluvial fan; and
- Glacial soils in the Fiddle Creek valley walls within the footprint of the Fiddle GMS.

### 2.4.5.14 Materials, Supplies, Chemical Reagents, and Wastes

Numerous materials, supplies, and chemical reagents would be used, including fuel, explosives, and ore processing reagents for the SGP. A SPCC Plan would be developed to establish procedures for responding to accidental spills and releases of petroleum products. In addition, a Hazardous Materials Handling and Emergency Response Plan would be developed to address procedures for responding to accidental spills or releases of hazardous materials to minimize health risks and environmental effects.

**Diesel Fuel, Gasoline, and Propane**

Aboveground storage tanks at the SGP would be used for fuels and other fluids, including gasoline, diesel fuel, lubricants, coolants, hydraulic fluids, and propane. Approximately 200,000 gallons of diesel fuel, 10,000 gallons of gasoline, and 30,000 gallons of propane would be stored at the SGP in addition to a variety of materials, supplies, and reagents (Table 2.4-11). Storage management would be outlined in the SPCC Plan. The storage tank facility for gasoline, diesel fuel, and propane would be located near the maintenance workshop with additional propane storage at the ore processing facility area, the underground portal area, and the worker housing facility.

**Explosives Storage**

Ammonium nitrate prill would be received in bulk in tanker trucks and transferred into storage silos. Other blasting supplies used for mine blasting operations would include blasting emulsion products, detonating cord, cast primers, and blasting caps. These products would be delivered in boxes or other approved containers on trucks. The explosives storage facility would include two silos containing ammonium nitrate on a concrete pad and two buildings, one for explosives and one for detonators. Components of bulk explosive material would be stored in separate and isolated containers, sized, and designed to meet Bureau of Alcohol, Tobacco, Firearms, and Explosives and MSHA requirements. The explosives storage facility would be fenced and securely gated. An explosives contractor would provide the products and manage the explosives storage facility.

**Miscellaneous Oils, Solvents, and Lubricants**

Various oils including motor oils, lubricants, antifreeze, and solvents would be shipped to the SGP on trucks. These would be stored in approved containers located within, or directly adjacent to, the maintenance shop and contained within secondary containments to prevent spills into the environment. All used petroleum products, waste antifreeze, and used solvents would be collected in approved containers, transported off site, and disposed or recycled.
**Miscellaneous Consumables**

Lime would be produced on site and stored in silos at the ore processing facility. Silos would be equipped with air emission controls. Sodium cyanide would be transported as dry cyanide briquettes to the SGP. Nitric and sulfuric acid would be transported in tanks designed to prevent spills even in the event of rollovers. Nitric and sulfuric acids would be stored in specialized non-corrosive, polyethylene-lined tanks located within the ore processing facility and would have secondary containment.

Miscellaneous consumables would consist of various reagents used in the ore processing facility, along with wear parts for the crushing and grinding circuits. Liquids would be shipped to the SGP in tank trucks designed for spill prevention and escorted to the SGP by pilot cars manned and equipped to handle spills. All reagents would be transported and stored in suitable containers in designated reagent storage areas.

**Waste Handling**

Wastes anticipated to be generated at the SGP include fluorescent bulbs, batteries, and empty aerosol containers which would be managed in accordance with the appropriate regulatory standards. Materials that are not consumed would be recycled, to the extent practical, or disposed of in accordance with applicable regulations.

Used petroleum products would be stored on site in approved containers that would be separate from other trash and garbage products. Used petroleum products would be transported off site for recycling or disposal in an approved facility.

Other legacy materials could be encountered during construction and operations. If encountered, these materials would be characterized to determine potential for re-processing, reuse, or on-site or off-site disposal.

2.4.5.15 Temporary Closure of Operations

No periods of temporary or seasonal closure are currently planned; however, a description of temporary closure is required for the SGP cyanidation permit if applicable. In the event of temporary suspension of mining activities, Perpetua would notify the Forest Service, USACE, IDEQ, IDWR, IDL, and Valley County in writing with as much advanced warning as possible of the temporary stop of mining activities. This notification would include reasons for the shutdown and the estimated timeframe for resuming production.

During any temporary shutdown, Perpetua would continue to implement operational and environmental maintenance and monitoring activities to meet permit stipulations and requirements for environmental protection. This would include the reclamation success monitoring.

Dewatering of the open pits may continue during temporary closure due to the negative effects that pit lake formation or highwall saturation would have on highwall stability and renewed mine operations. Since ore processing may not be occurring, excess water from the various facilities would need to be managed. The operational plans required by the Cyanidation Permit and other plans developed as part of IDEQ permits would also describe specific activities and provide details on how process water would be managed during a temporary closure.

A limited potential exists that unfinished facilities (such as haul roads, buttress, open pits, pit backfills, GMSs, etc.) would not have the same protective measures in place (e.g., stormwater collection systems or culverts) as would exist if the facility had been finished. Therefore, Perpetua would identify interim measures that would be taken to manage stormwater, sediment, dust, and other factors while the mining is temporarily stopped. Surface water diversion structures are all proposed to be installed prior to construction of the TSF, open pits, and the TSF Buttress; hence, surface water would be diverted around these facilities regardless of the stage of their completion.

Environmental reports would be submitted per previously agreed upon schedules. Regardless of the operating status of the mine, appropriate monitoring would continue until compliance with permanent regulatory closure requirements is attained, unless modified by the required regulatory authorities.

2.4.6 Surface and Underground Exploration

Surface and underground exploration including development drilling would occur to evaluate potential mineralized areas outside of the proposed mining areas. New surface and underground exploration activities would be conducted during construction and operations. Any additional future expansion of mining activities would require supplemental permitting and approvals, including additional evaluation under NEPA.

2.4.6.1 Surface Exploration

At any given time, disturbance associated with exploration activities conducted during construction and operations could include up to five acres of new temporary road disturbance and eight acres of drill pad disturbance on Forest lands at the SGP. Exploration sites would be reclaimed after completion of drilling. Disturbance resulting from surface exploration would total approximately 25 acres of roads and 40 acres of drill pads. Any jurisdictional stream crossings or impacts to jurisdictional wetlands could require
additional Section 404 CWA permits beyond those required for development and operation of the mine operations.

The exploration roads and drill sites would be located, as practical, on historical disturbance to avoid any identified cultural resources, other sensitive areas such as wetlands or Riparian Conservation Areas (RCAs), and potential impacts to habitat of ESA listed species. Figure 2.4-17 shows the boundary of the area within which ongoing surface exploration during construction and operations would occur.

Drill pad sizes would vary depending on the type of drilling equipment, number of holes to be drilled from the pad, and depth of drill hole. Drill pad sizes may range from approximately 0.05 to 0.15 acre.

Sumps and/or portable tanks would be used at each drill pad to collect drill cuttings and to manage and circulate drilling fluids. Sumps would be fenced and constructed with at least one side having a shallow grade for wildlife egress. Sumps would be backfilled and reclaimed when no longer needed for drilling.

Depending on the location of the drill pad, a variety of drill rigs and equipment would be supported by helicopter or terrestrial vehicle. Some drill holes may exceed 1,500 feet, but the average drill-hole depth would be approximately 800 feet. Drill holes would be both vertical and angled. Drilling activities also may include water exploration, dewatering well installation, and monitoring well installation. Water and non-toxic drilling fluids would be used for all drilling.

Dewatering and monitoring wells would be abandoned with surface completions/seals and be capped consistent with IDAPA 37.03.09 – Well Construction Standards Rules. Pre-collared holes would only be associated with track or truck mounted drilling equipment.

Areas disturbed for exploration would be contoured to blend into surrounding terrain; water bars and surface water channels would be retained to handle flows through the area. Compacted areas would be de-compacted as necessary prior to fertilizing and seeding.

Previously approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue as well.

2.4.6.2 Underground Exploration

Underground exploration activities could occur for the SGP throughout the life of the mine, such as the newly-discovered Scout Prospect, a 1-mile, downward-sloping tunnel (a decline). The decline would be used to reach the subsurface mineralized zone known as the Scout Prospect. The decline would be accessed from a portal facility known as the Scout Portal, located south of the planned ore processing facility (Figure 2.4-17). Approximately 100,000 tons of rock would be excavated from the decline. Exploration drill holes would be installed at various locations in the decline. Selected drill cuttings or core would be removed from underground for testing.

To construct the portal facility, the hillside would be cut into to develop a flat vertical slope using conventional underground drill and blast operations with mechanized equipment. Explosives would be used in the underground development process to construct the decline. The underground development
rock could be used for surface pad construction, hauled to the ore stockpile area, or hauled for storage in the TSF Buttress as appropriate.

Drilling is used in advance of the decline to ensure unexpected or unmanageable water pressures are not intersected. Water would be used in underground drilling or pumped from the collection point to the surface. Upon reaching the surface, this water would be piped to the ore processing facility to be used in the plant.

2.4.7 Closure and Reclamation

2.4.7.1 Overview

Closure and reclamation at the site would include interim, concurrent, and final closure and reclamation. Details on reclamation activities to be implemented for the SGP, including appropriate seed mixes to be used are described in the Reclamation and Closure Plan Stibnite Gold Project (Tetra Tech 2021a). Interim reclamation is intended to provide shorter-term stabilization to prevent erosion of disturbed areas and stockpiles that would be more fully and permanently reclaimed later.

Concurrent reclamation is designed to provide permanent, low-maintenance achievement of final reclamation goals on completed portions of the site prior to the overall completion of mining activities throughout the SGP. Approximately 37 percent of the reclamation would be completed concurrent to mining and ore processing; remaining reclamation activities would be completed during closure.

Final closure and reclamation would involve removing all structures and facilities; reclamation of those areas that have not been concurrently reclaimed such as the TSF and some backfill surfaces; recontouring and improving drainages; creation of wetlands; reconstructing various stream channels; decommissioning of the East Fork SFSR diversion tunnel; growth media placement; planting and revegetation on disturbance areas; and reopening Stibnite Road (FR 50-412) through the SGP.

Final reclamation of certain facilities could continue beyond the five-year closure and reclamation period. The Burntlog Route would be needed until the TSF is fully reclaimed, after which the newly constructed portions of the road would be decommissioned and reclaimed, and the currently existing portions of the road would be returned to their prior use.

Surface water flow diversion of portions of the East Fork SFSR, Garnet Creek, Meadow Creek, Midnight Creek, and Hennessy Creek would be reclaimed and incorporated into constructed wetlands (i.e., Garnet Creek) or restored stream channels across the reclaimed TSF (i.e., Meadow Creek) or Yellow Pine pit backfill.

Closure and reclamation activities would be intended to achieve post-mining land uses of wildlife and fisheries habitat and dispersed recreation at the SGP. Dispersed recreation uses would be accessible by the reopening of Stibnite Road (FR 50412) through the backfilled Yellow Pine pit that would facilitate recreational traffic and access to Thunder Mountain. The proposed final reclaimed condition of the site is shown on Figure 2.4-18. Concurrent and final closure and reclamation for the SGP are described in greater detail in the following sections.

Data Sources: Perpetua 2021a
Closure and reclamation activities would be intended to achieve post-mining land uses of wildlife and fisheries habitat and dispersed recreation at the SGP. Dispersed recreation uses would be accessible by the reopening of Stibnite Road (FR 50412) through the backfilled Yellow Pine pit that would facilitate recreational traffic and access to Thunder Mountain. The proposed final reclaimed condition of the site is shown on Figure 2.4-18. Concurrent and final closure and reclamation for the SGP are described in greater detail in the following sections.

ASAOC activities as described under the No Action Alternative would occur concurrent with 2021 MMP activities.

2.4.7.2 Decommissioning, Demolition, and Disposal of Facilities

Perpetua would dismantle or demolish structures and facilities not necessary for post-closure water management (e.g., certain culverts and pipelines). The materials from the dismantling or demolition of structures and facilities would be salvaged or disposed of in permitted off-site landfills. All reagents, petroleum products, solvents, and other hazardous or toxic materials would be removed from the site for reuse or would be disposed of according to applicable state and federal regulations. Concrete foundations would be broken or fractured as required to prevent excessive water retention and covered in-place with a minimum of 2 feet of a combination of 1.5 feet of backfill and 0.5 feet growth media or would be broken up and buried in the TSF Buttress or pit backfill prior to installation of a geosynthetic liner cover.

Soil/rock beneath fuel storage areas and chemical storage buildings would be tested for contamination and removed or disposed of appropriately if needed.

2.4.7.3 Underground Exploration and East Fork SFSR Tunnel

Perpetua would decommission and close underground facilities and underground support facilities, including the portals of the East Fork SFSR tunnel and Scout decline. To prevent future access to underground workings, the underground portals (i.e., East Fork SFSR tunnel and Scout decline) would be closed using concrete block bulkheads, rockfills, or a combination of rockfill and low-permeability foam. The downstream (north) East Fork SFSR portal and the Scout decline would be closed with bulkheads inside the portals (where overhead cover was at least 3 times the tunnel height) or backfilled with clean rockfill starting inside the portals and working outward, and up against the portal headwalls. Surface swales would be installed to direct surface water around the backfilled portal, and the exterior backfill, and surrounding disturbance would be graded to blend with adjacent topography, covered with growth media, and revegetated. At the East Fork SFSR upstream (south) portal, the control weir would be left in place, and the fishway weir notch raised with concrete, creating an approximately 4-foot-high sill to exclude river water or alluvial groundwater, and low-permeability geofoam or similar would be installed inside the portal after the initial backfill or bulkhead, to prevent water entry. Then, the portal area would be filled, regraded, and revegetated as described for the other openings.
2.4.7.4 Yellow Pine Pit

The majority of the Yellow Pine pit backfill material (90 percent) would be West End pit development rock. The balance of Yellow Pine pit backfill would include development rock from the Hangars Flat pit (5 percent) and the Yellow Pine pit (5 percent). Backfill would be placed in lifts not exceeding 100 feet in vertical height with the large equipment, to include selective placement of the top lifts by direct dumping to better control the type of rock that would be placed near the surface. This placement method also would limit subsidence of the backfill and the amount of regrading necessary prior to placement of growth media. This material would not be compacted beyond that which occurs during placement, subsequent routing of trucks, burial, and consolidation. Portions of the highwalls on the east and west sides of the pit would remain above the backfilled portion of the pit and would not be reclaimed. A sinuous channel would be constructed through the backfilled area for the reconstructed East Fork SFSR with an average valley gradient approximating the historical, pre-disturbance river gradient (Tetra Tech 2021b). A low permeability geosynthetic liner would be incorporated into the cover over the entire surface of the backfilled Yellow Pine pit, including the re-constructed channel floodplain corridor to reduce the infiltration of meteoric water into backfill material, which could dewater the restored stream channel and result in additional metal leaching from the underlying backfill. Above the geosynthetic liner in the stream corridor, a layer of relatively fine material would be placed to protect the stream liner from puncture, followed by coarse rock armor to protect from exposure via stream scour, followed by floodplain alluvium at a minimum thickness equal to the maximum estimated scour depth of the proposed stream channel. Growth media would then be placed and the area revegetated. The lined corridor would be wide enough to accommodate future channel migration, evolution, and over-bank flooding. The cover system outside the stream/floodplain corridor would be similar to that described for the TSF Buttress (Section 2.4.7.6). Portions of Hennessy and Midnight Creeks would be restored over the backfilled area along with the reconstructed East Fork SFSR.

Hennessy Creek would cascade over the approximately 275 feet tall west highwall of the Yellow Pine pit to a restored section of low-gradient channel on the western edge of the reconstructed East Fork SFSR floodplain before joining the restored East Fork SFSR channel. Midnight Creek would be restored across the southeastern portion of the reconstructed East Fork SFSR floodplain. After closure of the East Fork SFSR tunnel, backfilling of the Yellow Pine pit, and restoration of the East Fork SFSR and Hennessy Creek across the backfill, the Hennessy Creek diversion would be decommissioned and the area reclaimed, along with the adjacent operations-phase public access road.

To accommodate migrating fish, including Chinook salmon and bull trout, step pools would be established within the constructed East Fork SFSR channel. The vertical relief (drop) between successive pools would not exceed published fish passage criteria. Detailed hydrologic and hydraulic analyses would inform the overall channel and floodplain design and construction, with channel bankfull width approximately 25 to 30 feet, and average depth of approximately 2 feet. The lined Stibnite Lake, of similar size to the existing Yellow Pine pit lake, would be constructed within the lined corridor.

Access through the site to Thunder Mountain Road (FR 50375) would be reestablished with construction of an access road through the backfilled area, replacing the segments of the Stibnite Road (FR 50412) that were removed by mining.
2.4.7.5 West End Pit

West End Creek would be routed into the West End pit in a rock chute on the highwall adjacent to the upper legacy development rock dump, below which a pit lake would form in the main portion of the West End pit. The West End pit lake would fill gradually up to 400-feet-deep, and lake levels would fluctuate seasonally and with longer-term climate variations; however, the lake would not be expected to completely fill with water or spill due to the limited catchment area.

To account for model uncertainty, lake levels would be monitored after closure, as specified in the Environmental Monitoring and Management Plan (EMMP), and a threshold water level would be established, sufficient to contain the predicted runoff volume from a high-snowpack year without discharge. If water levels approach the threshold, either or both surface water diversion and water treatment could be implemented to prevent the lake from spilling. If needed, a temporary treatment unit would be mobilized to the site to treat and discharge the pit lake water until the lake level falls below the threshold discharge level, thus preventing untreated discharge in potential subsequent wet weather years and enabling gradual and predictable water treatment rather than treatment at higher but variable and uncertain peak spring runoff rates.

The Midnight pit, the approximately 6-acre, 100-foot-deep southeastern portion of the overall West End pit within the Midnight Creek catchment, would be backfilled during operations with approximately 6 million tons of development rock from the West End pit. The backfill would be placed to achieve a mounded final reclamation surface to promote drainage away from the West End pit and prevent formation of a pit lake within Midnight pit. Portions of the backfill would be covered with growth media and revegetated, and the remainder covered with talus like development rock to mimic a natural talus slope.

The floor of the sidehill pit southwest of the main West End pit would be graded to drain, covered with growth media, and revegetated. No backfilling would occur for the main West End pit. At closure, the remaining road into the pit and access to highwalls would be blocked with large boulders and/or earthen berms to deter motorized vehicle passage into the pit.

2.4.7.6 Tailings Storage Facility and TSF Buttress

Perpetua proposes to complete tailings reclamation approximately 9 years after ore processing operations cease. After tailings consolidate sufficiently to use heavy equipment on top of the tailings, starting approximately 3 to 5 years after the end of deposition, Perpetua would begin with placement of cover material, then construct wetlands and restore Meadow Creek and its tributaries within appropriately sized lined floodplain corridors, place growth media, and revegetate the area.

Once ore processing operations have ceased, Perpetua would begin removing the remaining supernatant water pool and ongoing accumulation of meteoric water and consolidation water through a combination of spray evaporators (similar to snowmaking misters) operated within the TSF boundary and an active water treatment that meets IPDES discharge limits, followed by discharge to the East Fork SFSR or Meadow Creek. Removal of the remaining supernatant water from the TSF would allow the surficial layers of the tailings to dry and gain strength, which would allow equipment to operate on the tailings surface for grading and the placement of the geosynthetic liner, overlain by unconsolidated overburden
and growth media. Concave areas in the consolidated tailings surface would be filled to create suitable drainage conditions prior to liner and cover installation in the area designed to become restored stream channel. Cover placement and minor grading of tailings would occur, beginning within 3 to 5 years from the end of deposition, as portions of the TSF surface dry enough to allow equipment traffic, working inward from the facility perimeter. The cover material overlying the geosynthetic liner would be sourced from unconsolidated overburden or other appropriate material stored in a GMS on top of the adjacent TSF Buttress.

Perpetua would restore appropriately designed meandering stream channels (Meadow Creek and tributaries) within a stream and floodplain corridor across the top of the lined TSF surface (Rio Applied Science and Engineering [Rio ASE] 2021). Pools and riffles would be constructed within the channel. Measures to create aquatic habitat would include side channels, oxbows, boulder clusters, root wads, and large woody debris. This would allow for the post-closure development of riparian habitat, convey water off the facility, and minimize potential interaction of surface water with the underlying tailings. Given the nature of the surface of the TSF, the constructed channel would have a shallow gradient.

Detailed hydrologic and hydraulic analyses would inform the overall channel and floodplain design, which would necessitate the construction of defined channels ranging from approximately 5 to 15 feet in bankfull width, with average bankfull depth reaching approximately 2 feet. A connected floodplain up to 200 feet wide would convey higher flows during a 100-year flood event.

Consolidation of the tailings would continue after cover placement and surface reclamation, at gradually declining rates, until approximately Mine Year 40. To prevent tailings consolidation water from mixing with surface water on the cover, potentially leading to water quality impacts if discharged to streams, the consolidation water would be collected for treatment, using shallow wells and gravel or geosynthetic drains. Initially, collected flows would be routed to a water treatment plant (WTP) for treatment and discharge. Treatment would no longer be required after approximately Mine Year 40, at which time the treatment facility would be decommissioned and the WTP site reclaimed.

Final slopes of the TSF Buttress would be variable, to blend with the surrounding terrain to the extent practicable, produce a permanent and stable landform, provide access for future maintenance on the TSF and buttress, and provide for non-erosive drainage across the reclaimed face of the buttress. Upon completion of final grading of the TSF Buttress, a low permeability geosynthetic cover would be placed over the facility, which would be designed to limit infiltration through the underlying development rock. The geosynthetic liner would be overlain by an inert soil/rock layer (non-potentially acid generating [PAG]/metal leaching development rock, fill, or alluvium) and growth media and revegetated. Similar to that for the TSF, a channel and floodplain corridor would be established for Meadow Creek across the top of the lined buttress. The channel would have a low gradient and wide floodplain across the top of the buttress, then drop more steeply to the valley floor near the south abutment. The steep channel segment would consist of a boulder chute that would flow through multiple energy-dissipating basins (one mid-slope and one at the toe of the TSF Buttress) before being discharged to a restored Meadow Creek on the valley bottom.
2.4.7.7 Hangar Flats Pit

Hangar Flats pit would be backfilled up to the valley bottom elevation or slightly higher and no pit lake is anticipated. The already-established Meadow Creek diversion channel and floodplain corridor would be retained around Hangar Flats pit as the final configuration, and the segment of Meadow Creek between the toe of the TSF Buttress and the entrance to the Hangar Flats pit diversion would be restored along with adjacent riparian wetlands. At closure, the entire surface of the backfilled Hangar Flats pit would be covered with a low permeability geosynthetic liner overlain with seed bank material to establish wetlands. Non-perennial drainages in adjacent upland areas would be routed to facilitate development of the wetland hydrology. Meadow Creek downstream of the Hangar Flats pit diversion, to the confluence with the East Fork SFSR, would be enhanced during mine operations with large woody debris, boulder cluster habitat structures, and riparian plantings.

2.4.7.8 Transmission Line and Electrical Infrastructure

The Johnson Creek and Stibnite substations would not be decommissioned immediately during mine closure; the transmission line between these substations would remain to provide power for post-closure water treatment. Once there is no longer a need for active water treatment, Perpetua, in coordination with IPCo, would disassemble the approximately 9-mile transmission line between the Johnson Creek and Stibnite substations. The substations, switchgear, and power line would be removed. The transmission line ROW and associated access roads would be recontoured to match surrounding topography and revegetated. As part of revegetation, the transmission line structure pads and access roads would be scarified and revegetated. Revegetation would not be required on affected lands, or portions thereof, where planting is not practicable or reasonable because the soil is composed of excessive amounts of sand, gravel, shale, stone, or other material to such an extent to prohibit plant growth (IDAPA 20.02.02).

2.4.7.9 Burntlog Route

Once all final mine closure/reclamation work has been completed, Perpetua would reduce the 21-foot-wide travel way of 19.8 miles of Burntlog Road (FR 447), 1.3 miles of Meadow Creek Lookout Road (FR 51290), and 2 miles along Thunder Mountain Road (FR 375) of the Burntlog Route to their approximate pre-mining width. Returning this 23 miles of existing road to pre-mining condition would entail grading and/or scarification along the outside edges of the road followed by seeding with the species listed in the Reclamation and Closure Plan (Tetra Tech 2021a) or as approved by the Forest Service. Perpetua would remove ditches, cross drains, culverts, safety berms, mile markers, guardrails, and signs on roads if these features are no longer needed. These roads would retain the flatter grades and gentler curves constructed for mine operations.

The approximately 15 miles of Burntlog Route that was newly constructed for the SGP, connecting Burnt Log Road (FR 447) to Meadow Creek Lookout Road (FR 51290) and Thunder Mountain Road (FR 50375) would be fully decommissioned. The road would be decommissioned by pulling back and recontouring road cuts to slopes that are similar to, but not necessarily matching, pre-project conditions, and that would be consistent with the surrounding terrain as practicable. Surface water diversions, cross drains, culverts, safety berms, mile markers, guardrails, and signs would be removed. Soil nail walls, constructed of anchors bolted into the ground with a sprayed concrete surface, would remain to support slopes in areas with soft soils or weathered rock. Water bars or other erosion and sediment control
structures, armored stream crossings, and stormwater crossings would be included where necessary. The
reclaimed areas would be scarified, and 6 inches of growth media would be placed in upland areas,
followed by seeding and certified weed-free mulching on slopes over 30 percent. Revegetation would not
be required where planting is not practicable or reasonable due to excessive amounts of sand, gravel,
shale, stone, or other material to such an extent to prohibit plant growth (IDAPA 20.02.02).

2.4.7.10 Post Closure Public Access

As mentioned in Section 2.4.7.4, a service road would be established over the backfilled Yellow Pine pit
to allow public access through the reclaimed site and connect Stibnite Road (FR 50412) to Thunder
Mountain Road (FR 50375) (Figure 2.4-18).

2.4.7.11 Off-site Facilities

Following mine closure and reclamation, the Burntlog Maintenance Facility buildings would be removed.
The sewer system and septic tanks for the Burntlog Maintenance Facility would be decommissioned. All
reagents, petroleum products, solvents, and other hazardous or toxic materials would be removed from the
site and disposed of according to applicable state and federal regulations. Soil/rock beneath fuel storage
areas and chemical storage buildings would be tested for contamination and treated if necessary. After
demolition of the buildings and facilities, the site would be graded, and drainage restored.

Perpetua has identified a “light industry” post-mining land use for the SGLF in which the facility could be
maintained by a third party for future use, meaning the facility, located on private land, would not be
reclaimed. A new conditional use permit (CUP) from Valley County would be required prior to use by
any other entity. If there is no further use of the site after a two-year period, the structures would be
removed and the site reclaimed (Valley County CUP No. 20-12 Stibnite Gold Project - Logistics Facility).

2.4.7.12 Contouring, Grading, Growth Medium Placement, and Seeding

Except for the Hangar Flats pit highwall above the valley bottom, the West End pit, and a portion of the
Yellow Pine pit highwall, Perpetua would contour and grade disturbed areas to blend into the surrounding
topography and terrain. Compacted areas such as roads, ore stockpile areas, parking lots, fuel storage
areas, and building sites would be prepared prior to placement of growth media and revegetation. Haul
routes and access roads would be re-contoured to establish natural drainage patterns.

Growth media suitability criteria include USDA texture, percentage of organic matter, course fragment
percentage and acidity (pH). Root zone material suitability guidelines include USDA texture, course
fragment percentage, soil acidity (pH), electroconductivity, sodium adsorption ratio, Net Acid Generation
(NAG) pH, bulk density and arsenic, antimony, and mercury levels. Perpetua would manufacture growth
media material using screened fines from glacial till sources, available mulched vegetation, and off-site
composted material from private lands. Off-site sources for composting feedstock materials would be in
compliance with Forest Service requirements.

Planting, seeding, and mulching would be conducted in the fall and early winter to take advantage of
snowpack and springtime moisture. Where cover crops are used in lieu of mulch, seeding would occur in
the spring or fall followed by seeding of the permanent mixture. The forbs, grass species, seed amounts,
and the trees and shrubs planned for planting on reclaimed areas are described in Tetra Tech (2021a) and would be approved by the Forest Service.

2.4.7.13 Post Closure Water Treatment

Evaluation of post-closure water treatment is ongoing. For the 2021 MMP, Perpetua has indicated that sources of water that could require treatment during closure and reclamation and through the post-closure period include TSF runoff and tailings consolidation water, plus any TSF Buttress toe seepage.

As previously described, consolidation water would be withdrawn from beneath the TSF geosynthetic cover using a combination of wells, wicks, and/or gravel drains, and routed to water treatment. Collected flows would be routed to the water treatment plant for treatment and discharge. Once it is determined that treatment is no longer required based upon agency approvals, the treatment facility would be decommissioned and the WTP site reclaimed. Water treatment would be provided during the reclamation and closure and post-closure phases until waters requiring treatment are no longer being generated. Life-of-mine water treatment of the TSF and other facilities is discussed in Section 2.4.5.10.

As described in Section 2.4.7.5, if spillage of surface water from the West End pit lake becomes imminent, a portable system would be brought to the site to treat and discharge pit lake water to maintain levels below the rim of the lake and prevent uncontrolled release of lake water.

2.4.7.14 Closure and Reclamation Financial Assurance

As part of the approval for the SGP, Perpetua would be required to post financial assurance to ensure that NFS lands and resources involved with the mine operations are reclaimed in accordance with the approved plan of operations and reclamation requirements (36 CFR 228.8 and 228.13). This financial assurance would provide adequate funding to allow the Forest Service to complete reclamation and post-closure operation, including continuation of any post-closure water treatment, maintenance activities, and necessary monitoring for as long as required to return the site to a stable and acceptable condition in the event Perpetua was unable to do so. The amount of financial assurance would be determined in collaboration with the Forest Service and would “address all Forest Service costs that would be incurred in taking over operations because of operator default” (Forest Service 2004). The financial assurance would be required in a readily available bond or other instrument payable to the Forest Service. To ensure the bond can be adjusted as needed to reflect actual costs and inflation, there would be provisions allowing for periodic adjustments in the final plan of operations prior to approval. Calculation of the initial bond amount would be completed following the Record of Decision (ROD) when enough information is available to adequately and accurately perform the calculation. In addition to the Forest Service-required bond, mitigation under Section 404 of the CWA also requires financial assurance.

The IDL would require a bond as part of their permitting authority and IDEQ would require a bond for the cyanidation permit which would then be held by IDL. The IDWR is the state agency responsible for design review and approval of the TSF. IDWR also would require a bond so that the TSF can be placed in a safe maintenance-free condition if abandoned by the owner.
2.4.7.15 Closure and Reclamation Traffic

Most closure and reclamation traffic would occur May through November. Mine traffic during closure and reclamation is anticipated to result in a total AADT of 27, with 15 being from heavy vehicles and 12 being from light vehicles.

2.4.8 Monitoring

Air emissions, groundwater, surface water, aquatic, and other environmental parameters would be monitored during mine construction, operation, closure, and post-closure as described and specified in the EMMP (Brown and Caldwell 2021c). Authorizations from federal and state agencies include monitoring requirements for resources (e.g., air emissions, surface water, and groundwater) during mine construction, operation, closure and reclamation, and post-closure. Mitigation measures and monitoring actions would not be known fully until required permits have been issued.

Monitoring would be conducted following the completion of closure and reclamation of all facilities and disturbance areas to demonstrate compliance with permit requirements and to measure the success of reclamation and mitigation. Final monitoring requirements and timelines would be outlined in the final permit approval documents and the final EMMP.

The final EMMP would consist of multiple component plans, each of which would be finalized upon issuance of the related permit(s) and would contain monitoring and management requirements from each permit. In some cases, if environmental outcomes may be uncertain, the EMMP could include adaptive management planning which requires identification of performance measures, impact thresholds, and operational adjustment options, all intended to achieve and demonstrate compliance with applicable permitting and/or consistency with the environmental analysis.

2.4.8.1 Environmental Monitoring

The EMMP (Brown and Caldwell 2021c) provides an overview of the actual or anticipated monitoring and/or management requirements for each of the required regulatory permits and establishes Perpetua’s commitments to environmental monitoring and management of mine facilities and environmental resources. The EMMP would allow Perpetua to monitor its operations and environmental commitments, document permit compliance, and reduce potential impacts to environmental resources. The EMMP describes the component monitoring and management plans that would be developed and used by Perpetua to manage water resources, monitor mine facilities, and monitor environmental and cultural resources. The EMMP includes environmental tasks and lists environmental permits, licenses, authorizations, and corresponding obligations.

2.4.8.2 Reclamation Monitoring

Prior to reclamation monitoring and maintenance programs, the Forest Service and IDL would agree to specific quantitative and qualitative reclamation monitoring plans and standards.

Reclamation monitoring would begin during concurrent reclamation at SGP facilities. Quantitative and qualitative monitoring of reclamation success would begin the first growing season after concurrent or final reclamation is completed and would continue until success criteria are satisfied. The Reclamation
and Closure Plan (Tetra Tech 2021a) presents the quantitative and qualitative reclamation monitoring that would be conducted and the performance standards that would be used (with Forest Service and IDL approval) to determine when maintenance activities are necessary, or reclamation is complete. These monitoring requirements are summarized below.

Erosion and Sediment Control Monitoring

Soil stability would be estimated for all reclaimed areas using qualitative descriptors. A reclamation specialist would observe each reclaimed area and assign qualitative descriptors. The observations would be completed twice annually for erosion control purposes, once in the spring and once in the fall; and after three years for performance monitoring purposes. For performance monitoring, the observations would be made at the same time the vegetation success observations are made. The monitoring results would be used to aid in determining the cause of any failures that are encountered and to locate problem areas before erosion becomes widespread enough to affect reclamation success.

Slope Stability Monitoring

Slope stability would be monitored during the erosion observations. Qualified staff would look for signs of slope movement, cut slope and rock face failures, and other indications of slope instability. The location and dimensions of significant surface cracks and fill slope bulges would be monitored. This information would be used to determine if surface cracks are the result of differential settling of fill material or slope instability. The appropriate regulatory agency would be notified, and corrective plans would be developed.

Reclamation Maintenance Procedures

If the performance of reclaimed areas is not satisfactory, appropriate maintenance activities would be implemented. Maintenance activities may include one or more of the following:

- Sediment removal from sediment basins, stormwater drainage channels, and diversions as necessary to maintain their design capacity;
- Diverting surface water away from reclaimed areas where erosion jeopardizes attainment of reclamation standards;
- Stabilizing rills, gullies, and other erosion features or slope failures that have exposed development rock;
- Noxious weed and invasive plant species control; and
- Re-seeding or re-applying reclamation treatments in areas where it is determined through monitoring and agency consultation that reclamation would not meet standards.

Annual Report

Perpetua would submit an annual report to the Forest Service and the other federal and state agencies that are responsible for issuing authorizations applicable to reclamation for the preceding calendar year. The annual report would contain descriptions of the reclamation activities completed during the previous year,
a summary of areas reclaimed, a discussion of the results of the reclamation monitoring conducted, and corrective actions implemented.

## 2.4.9 Environmental Design Features

The SGP must comply with all laws and regulations that apply to the proposed activities (Table 2.4-12). Standards and guidelines in the Boise Forest Plan and Payette Forest Plan (Forest Service 2003a, 2010a) that are designed to reduce or prevent undesirable impacts resulting from proposed management activities are incorporated into the action alternatives by reference. In addition, best management practices outlined in the Best Management Practices for Mining in Idaho (IDL 1992) would be implemented where appropriate and applicable for operations to minimize site disturbance from mining and drilling activities.

In the design of the 2021 MMP, Perpetua has already considered many of the potential environmental impacts that might be caused by the SGP. This has led to an internal evaluation of project design features and operational characteristics that may have the effect of reducing and/or eliminating potential environmental impacts of the SGP. Such project-specific measures intended by a proponent to inherently reduce and/or avoid potential environmental impacts of a proposed action are referred to as environmental "design features".

Based on the application of permits and regulatory compliance requirements to the project, regulatory requirements, standards and guidelines, best management practices, and likely permit conditions are listed in Table 2.4-12. The environmental design features (EDFs) beyond regulatory requirements that have been proposed and committed to by Perpetua are listed in Table 2.4-13. The impact analysis and environmental consequences takes these EDFs as well as regulatory requirements into consideration, such that the identified potential impacts of the SGP would be those that remain after their application. These EDFs and regulatory requirements would be applied to reduce and minimize impacts to resources from the SGP.

<td>During off-loading of fuel from fuel vehicles or during refueling operations have a standard marine-type fuel containment boom (which would be of sufficient length for a worst-case discharge), spill prevention kit, and fire kit readily available on site. Store two or more spill containment/response caches along each of the fuel delivery routes. Spill response team will carry sufficient containment equipment for one full fuel tanker. Include the Forest Service as a party to be notified in the event of a hazardous materials spill. Intake pumps, engines, fuel storage, fuel containment site, and other equipment with fuel or lubricants would be inspected at each refueling and periodically between refueling for leakage or spillage. Pilot and emergency spill response vehicles would carry appropriate containment and first aid equipment. All fuel containers would be marked with contents, owner’s name and contact information. Material Safety and Data Sheets for all products would be posted and available on site with the SPCC plan. Intake pumps would not be situated within the active stream/ditch channel and would be placed within containment vessels capable of holding 120 percent of the pump engine’s fuel, engine oil and hydraulic fluid. The smallest practical pump and intake hose would be used. Following large storm events, the intake pumps would be inspected to determine if stream flow has encroached into the pump area and if the pump needs to be moved so it remains above flowing water. A spill prevention and clean-up kit would be placed at the intake pump site and would consist of absorbent pads and/or boom (which would be sufficient length for a worst-case discharge), drip pan, a shovel, and a fire extinguisher. Spare fuel for the water intake pump would be stored in approved [29 CFR 1926.152(a)(1)] fuel storage containers placed into a secondary containment vessel capable of holding at least 120 percent of the volume of the fuel in the fuel container. A copy of the SPCC plan would be kept at an appropriate on-site facility. Unless otherwise authorized, all garbage or refuse should be removed from NFS lands. This includes, but is not limited to, empty fuel and lubricant containers. Food and garbage would be stored either indoors, in vehicles, or if outside, in wildlife-proof containers. No garbage would be burned.</td>

</tr>
</tbody>
</table>
Materials such as hay, straw, or mulch that are used for rehabilitation and reclamation activities shall be free of noxious weed seed and shall comply with the 1995 weed-free forage special order against use of non-certified hay, straw, or mulch. Materials that are not covered under a weed seed free certification, and that have the potential to contain noxious weed seed, shall be inspected and determined to be free of weed seed before purchase and use.

Source sites for gravel and borrow materials shall be inspected for noxious weeds before materials are processed, used, or transported from the source site into the project area or onto the National Forest.

Gravel or borrow material source sites with noxious weed species present shall not be used unless effective treatment or other mitigation measures are implemented.

To prevent invasion/expansion of noxious weeds, the following provisions will be included in the plan of operating where land-disturbing activities are associated with the authorized land use):

a) Re-vegetate areas, as designated by the Forest Service, where the soil has been exposed by ground-disturbing activity. Implement other measures, as designated by the Forest Service, to supplement the influence of re-vegetation in preventing the invasion or expansion of noxious weeds. Potential areas would include: construction and development sites, underground utility corridors, skid trails, landings, firebreaks, slides, slumps, temporary roads, cut and fill slopes, and travel ways of specified roads.

b) Earth-disturbing equipment used on National Forest System lands--such as cats, graders, and front-loaders--shall be cleaned to remove all visible plant parts, soil, and material that may carry noxious weed seeds. Cleaning shall occur prior to entry onto the project area and again upon leaving the project area if the project area has noxious weed infestations. This also applies to fire suppression earth-disturbing equipment contracted after a Wildland Fire Situation Analysis/Wildland Fire Implementation Plan has been completed.

<td>Design Feature developed for compliance with BNF: WIGU17</td>
<td>Wildlife</td>
</tr>
<tr>
<td>To minimize adverse effects of lighting to TEPC, MIS, or Sensitive species, where necessary and in accordance with MSHA and the Occupational Safety and Health Administration (OSHA), the proponent could utilize actions in line with, but not limited to, the below: To the extent practicable, limit construction activities to the time between dawn and dusk. Utilize, where possible, use down shielding or directional lighting such as 'Cobra' style lights rather than an omnidirectional light system. While allowing for public and worker safety, utilize low intensity energy saving lighting (e.g., low pressure sodium lamps). If possible, minimize illumination of lighting on associated construction or operation structures by using motion sensors or heat sensors.</td>
<td>Design Feature</td>
<td>Design Feature developed for compliance with BNF and PNF: WIST03, WIST04 TEST29</td>
<td>Wildlife</td>
</tr>
</tbody>
</table>
If possible, place light shields over outside lights, confining light to the immediate area. Whisper Quiet light plants could be utilized used to mitigate visual impacts from night operations.

Communication towers should not be sited in or near wetlands, or other known bird concentration or high use areas (e.g., riparian corridors), in known migratory or daily movement flyways. Towers should not be sited in areas with a high incidence of fog, mist, and low ceilings.

To minimize adverse effects of noise to TEPC, MIS, or Sensitive species, where necessary and in accordance with MSHA and OSHA, the proponent could utilize actions in line with, but not limited to, the below:

- Construction equipment engines would be equipped with adequate mufflers, intake silencers, and engine enclosures when feasible.
- When practicable, pumps, generators, and engines would be turned off when not in use.
- Temporary wooden structure could be erected around portions of the drill, pumps, and heaters, with acoustic absorbent panels. These temporary structures would not be put in place if they created safety issues related to exhaust vapor build-up.
- When feasible, activities such as helicopter use and blasting, could be scheduled at the same time.

Design and implement projects within occupied habitats of Sensitive species to help prevent them from becoming listed. Use Forest Service-approved portions of Conservation Strategies and Agreements, as appropriate, in the management of Sensitive species habitat to keep management actions from contributing to a trend toward listing for these species.

### Table 2.4-13  Proponent Proposed Design Features

<tr>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>All off-highway diesel engines would be EPA Tier IV or better.</td>
<td>Air Quality, Climate Change</td>
</tr>
<tr>
<td>Perpetua would encourage employees to use company provided shuttle buses as transport to the SGLF from towns along SH 55.</td>
<td>Air Quality, Health and Safety, Transportation and Access</td>
</tr>
<tr>
<td>Busing and/or vanpooling would be provided for Perpetua and contractor employees. The associated parking area would accommodate approximately 300 vehicles. To the degree practicable, Perpetua would mandate the use of busing and vans for employee and contractor transportation to the SGP and the worker housing facility.</td>
<td>Air Quality, Health and Safety, Transportation and Access</td>
</tr>
<tr>
<td>Proper dust control would be employed along transportation corridors and active mining areas using aquatic safe dust suppression chemicals and methods.</td>
<td>Air Quality, Water Resources, Fish, Wildlife</td>
</tr>
<tr>
<td>Perpetua would utilize “smart grid” technology to reduce energy consumption, such as auto dimming lights in offices.</td>
<td>Climate Change</td>
</tr>
<tr>
<td>Perpetua employees and contractors would be informed about relevant governmental regulations intended to protect cultural and historic resources.</td>
<td>Heritage</td>
</tr>
<tr>
<td>To protect fish residing in, using, or potentially using the Yellow Pine Pit lake (Chinook salmon, steelhead trout, bull trout, Westslope cutthroat trout, mountain whitefish), Perpetua has developed a Fish Salvage and Release Plan to isolate the lake from upstream movement into the lake and salvage and release fish. The Fish Salvage and Release Plan would be refined in coordination with federal, state, and tribal agencies. Perpetua would, in consultation with the USFWS and the NMFS (the Services), design, install, and operate a fish trap and one or two weirs designed to allow fish to leave the Yellow Pine pit lake but not allow fish to migrate upstream past the trap to ensure that the fewest number of individual ESA-listed fish species are present in the pit lake when the draining process begins. The timing for providing the upstream barrier to fish movement would be designed to minimize the number of fish in the Yellow Pine pit lake, particularly larger bull trout. Fish captured in the Yellow Pine pit lake would be immediately released downstream of the upstream fish movement barrier or in another location determined by the appropriate regulatory agencies. The Yellow Pine pit lake would be partially drained to recover the remaining fish and relocate them prior to final draining of the pit lake. A fishway has been designed and would be operated within the East Fork SFSR tunnel to provide upstream and downstream volitional fish passage throughout mine operations. The East Fork SFSR diversion tunnel would be approximately 0.9 miles long and 15 feet high by 15 feet wide. The tunnel would include a parallel accessway to allow equipment and personnel access for monitoring, inspection, and maintenance. The accessway would function as a floodway for high flows, limiting the operating flow range within the fishway while river and thus total tunnel flows vary more widely. As an alternative to the fishway in the East Fork SFSR tunnel Perpetua would provide adult passage by trap and haul if needed. Criteria may be put in place so that if any unusual or unexpected events occur that result in adverse impacts to fish during operations, fish passage through the fishway would be switched to trap and haul operations.</td>
<td>Fish</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>Low-energy lighting would be provided in the fishway to determine if it aids in fish passage and to provide light for tunnel and fishway inspections. The system would be configured so that it mimics the photoperiod of the region, run manually on a dimming system, or be completely turned off at the option of the operator.</td>
<td>Fish</td>
</tr>
<tr>
<td>Fish salvage and relocation operations would be conducted any time the facility needs repair within the fishway, potentially during sediment removal, and potentially when streamflows recede from the accessway.</td>
<td>Fish</td>
</tr>
<tr>
<td>Post mining, the East Fork SFSR stream channel would be reestablished across the backfilled Yellow Pine pit with a channel design that would provide for upstream and downstream fish passage.</td>
<td>Fish</td>
</tr>
<tr>
<td>Perpetua would reestablish fish passage at the location of the existing box culvert on the East Fork SFSR just downstream of the confluence with Meadow Creek at the McCall-Stibnite Road (CR 50-412) crossing.</td>
<td>Fish</td>
</tr>
<tr>
<td>Perpetua would improve fish passage along the Burntlog Route within the SGP area by identifying and replacing existing collapsed, undersized, or otherwise degraded or poorly designed culverts at road crossings and committing appropriate resources to fix and improve these structures.</td>
<td>Fish</td>
</tr>
<tr>
<td>Perpetua would install side-ditching, culverts, guardrails, and bridges, where necessary along the Burntlog Route, with design features to provide fish passage and limit potential sediment delivery to streams.</td>
<td>Fish</td>
</tr>
<tr>
<td>Perpetua would employ blasting setback distances and other controlled blasting techniques following industry best management practices (modifying blasting variables including charge size, and vibration and overpressure monitoring) to minimize impacts to fish from blasting. Perpetua would follow up with monitoring in early stages of operation to evaluate effectiveness and refine blasting protocols in coordination with federal, state, and tribal agencies, if needed.</td>
<td>Fish</td>
</tr>
<tr>
<td>Dewatering of the Yellow Pine pit lake or stream segments would generally be conducted during low-flow periods to facilitate stream segment isolation and fish salvage. When practicable, dewatering also would be timed to avoid or minimize impacts during known spawning periods for Chinook salmon, steelhead, and bull trout.</td>
<td>Fish</td>
</tr>
<tr>
<td>To protect fish, Perpetua would develop a standard procedure for channel segment isolation, dewatering, fish salvage, and fish relocation to appropriate receiving streams during dewatering or maintenance of natural stream and diversion channels, based on the USFWS Recommended Fish Exclusion, Capture, Handling, and Electroshocking Protocols and Standards (USFWS 2012) and refined in coordination with federal, state, and tribal agencies.</td>
<td>Fish</td>
</tr>
<tr>
<td>The fishway operations and management plan (FOMP) defines the monitoring and evaluation plan elements and describes how the hydraulic conditions, fish use, and performance of the tunnel fishway would be measured and evaluated, and the design of the adaptive management component of the plan including the option of using trap and haul.</td>
<td>Fish</td>
</tr>
<tr>
<td>Access and SGP haul road crossings of fish bearing streams would be designed such that structures installed or constructed allow fish passage.</td>
<td>Fish and Wildlife</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Perpetua would implement measures to limit stream baseflow effects during active operations, including a combination of lining key reaches of streams potentially impacted by pit dewatering, and treating and discharging pit dewatering water that is not used for ore processing or other industrial uses. Maintain instream flows for fish species and other aquatic resources: flows within natural stream channels affected by SGP operations would be maintained to meet seasonally appropriate and stream-specific low-flow needs to the maximum extent practicable. Perpetua would continue to evaluate options and measures to further avoid and minimize the magnitude and duration of effects of the SGP through other measures in consultation with federal, state, and tribal agencies.</td>
<td>Fish, Water Resources</td>
</tr>
<tr>
<td>Following permanent cessation of mining activities at the Yellow Pine pit, Perpetua would backfill the pit and route the East Fork SFSR over the backfilled pit with a longer, lower-gradient channel with higher intrinsic potential for Chinook salmon and steelhead spawning and rearing than the channel that exists presently. The floodplain area along the constructed channel would include side-channels and other off-channel features and would be revegetated to restore wetland and riparian habitat providing long-term shade/cover favorable to fish.</td>
<td>Fish, Wetlands</td>
</tr>
<tr>
<td>The Meadow Creek channel would be routed over the final TSF and TSF Embankment and Buttress, resulting in a long, relatively flat surface and a short, steep face. On top of the TSF surface, Meadow Creek would be contained within a broad floodplain corridor bound laterally by erosion-resistant terraces and vertically by a subsurface armor layer over a low-permeability stream liner.</td>
<td>Fish, Wetlands</td>
</tr>
<tr>
<td>Perpetua would stabilize and restore Blowout Creek. Blowout Creek wetland restoration would consist of restoring and enhancing palustrine aquatic bed (PAB), palustrine emergent (PEM), Palustrine scrub-scrub (PSS) wetlands that were impacted when a historical dam failed on Blowout Creek. Headcutting and shallow aquifer dewatering have impaired and reduced functions of the wetland vegetation classes. A grade control and groundwater cutoff structure is proposed to raise the water level in Blowout Creek as well as recharge the shallow groundwater system and reduce stream headcutting. A coarse rock drain would be constructed within the chute downstream of the failed dam to isolate the flow of Blowout Creek from the actively eroding chute side slopes and to prevent further erosion of the gully bottom, facilitating subsequent restoration of a surface channel on top of the drain. Perpetua would stabilize the steep, confined, erosive middle reach to address the significant fine sediment load currently produced from this reach and restore the downstream, relatively low-gradient reach.</td>
<td>Fish, Wetlands, Water Resources</td>
</tr>
<tr>
<td>Perpetua would lead annual site visits for USACE, EPA, IDFG, and other interested agency personnel as needed to facilitate agency review of mitigation areas if desired. Final reporting and data archival requirements would be subject to permit conditions; however, it is anticipated that until the USACE concurs that mitigation sites meet success criteria, monitoring reports would be prepared by Perpetua annually and submitted to USACE Walla Walla District, EPA, IDFG, IDL, National Oceanic and Atmospheric Administration (NOAA) Fisheries, USFWS, the Forest Service, and other interested agencies, SGP partners, and stakeholders. After success criteria are met, permit conditions will set the frequency for long-term monitoring and reporting.</td>
<td>Fish, Wetlands, Water Resources</td>
</tr>
<tr>
<td>Perpetua would repair and rehabilitate habitats adversely affected by historical mining impacts in the SGP area within the disturbance footprint of the modified mine plan.</td>
<td>Fish, Wetlands, Water Resources</td>
</tr>
<tr>
<td>Minor surface improvements (e.g., ditch and culvert repair, adding gravel, winter snow removal, and summer dust suppression) would occur on the Yellow Pine Route to reduce sediment runoff and dust generation.</td>
<td>Fish, Wildlife, Water Resources</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------</td>
</tr>
<tr>
<td>Implementation of an avalanche hazard management program that &quot;could&quot; include avalanche control and/or road closure. Also proposed is daily region-scale assessments; daily weather observations including snowpack and avalanches; notifying SGP staff of highly unstable conditions; closing roads during periods of elevated hazard or blocked roads; and controlling avalanche initiation with explosives. Section 7.2 of DAC (2021) provides a description of an active avalanche monitoring and control program that has more specific descriptions of the components that could be included in an SGP-specific plan. Section 8.0 of Dynamic Avalanche Control (DAC; 2021) includes a discussion of avalanche controls likely to be necessary for the avalanche paths identified and this should be included in the program discussed above. Perpetua would provide for Forest Service review a written avalanche monitoring and control program that could be implemented for the SGP.</td>
<td>Geotechnical Hazards</td>
</tr>
<tr>
<td>Construction and operation of snow catchment areas for smaller avalanche paths. Section 7.3 of DAC (2021) includes a more detailed discussion of specific locations and design characteristics for ditches and catchment areas to reduce avalanche impacts to roads. Perpetua would review this information and current road designs to provide for Forest Service review specific designs and maintenance/operating plans for said ditches and catchment areas along the selected access route.</td>
<td>Geotechnical Hazards</td>
</tr>
<tr>
<td>Avalance structural defense options that could be beneficial in the SGP mine site to protect high-value, stationary facilities from avalanche hazards. Perpetua would review this information and provide the Forest Service with any recommendations for implementing structural avalanche defenses in at the SGP mine site.</td>
<td>Geotechnical Hazards</td>
</tr>
<tr>
<td>Perpetua would increase the ground limestone dosage to the pre-oxidized concentrate as it is fed into the autoclave to address the potential for creation of soluble arsenic. By decreasing the free acid levels (increasing the pH) in the autoclave by increasing the ground limestone dosage in the autoclave feed increases the quantity of crystalline (stable) arsenic compounds in the resultant slurry with a proportional decrease in the quantity of amorphous (unstable) arsenic compounds.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Perpetua would monitor levels of soluble arsenic in the tailings. If soluble arsenic levels are higher than anticipated, Perpetua would treat the oxidized concentrate with HAC prior to neutralization.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>The ore processing area would be designed to provide for containment of ore processing materials, chemicals, wastes, and surface runoff. Potentially hazardous chemicals and wastes would be stored within buildings or areas with both primary and secondary containment. Surface runoff within the ore processing area would be directed to a contact water pond for collection. Leaks or spills escaping primary and secondary containment would flow to the contact water pond for collection and would not discharge off site.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>The processing circuit would be housed in a steel frame building set on concrete foundations with interior curbing to provide secondary containment; the interior curbing would be high enough to contain 110 percent of the volume of the largest tank.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>The gold and silver leaching circuit would be designed and operated consistent with the International Cyanide Management Institute Code (ICMC) (<a href="https://www.cyanidecode.org">https://www.cyanidecode.org</a>) and the Initiative for Responsible Mining Assurance (IRMA) Standard for Responsible Mining (<a href="https://responsiblemining.net/resources/">https://responsiblemining.net/resources/</a>). Accordingly, impermeable secondary containment for cyanide unloading, storage, mixing and process tanks shall be sized to hold a volume at least 110 percent of the largest tank within the containment and any piping draining back to the tank, with additional capacity for the design storm event, if applicable. Pipelines containing process water or process solution shall also use secondary containment in combination with audible alarms, interlock systems, and/or sumps as spill control measures.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>Cyanide-bearing solutions used in ore processing would be neutralized to approximately 10 milligrams per liter weak acid dissociable (WAD) cyanide before the material is pumped to the TSF. Residual cyanide would be treated using a sodium metabisulfite and air system to detoxify the cyanide by oxidation to form cyanate.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Cyanide would be neutralized to levels protective of wildlife, and the TSF would be surrounded by an 8-foot high, chain-link fence designed to keep wildlife, such as deer and elk, from entering the impoundment area, to prevent either liner damage or wildlife drowning.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Oils, solvents, and lubricants would be stored in approved containers located within, or directly adjacent to, the maintenance shop and contained within secondary containments to prevent spills into the environment. All used petroleum products, waste antifreeze, and used solvents would be collected in approved containers, transported off site, and disposed or recycled.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Nitric and sulfuric acid would be transported in tanks designed to prevent spills even in the event of rollovers.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Nitric and sulfuric acids would be stored in specialized non-corrosive, polyethylene-lined tanks located within the ore processing facility and would have secondary containment.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Liquids would be shipped to the SGP in tank trucks designed for spill prevention and escorted to the SGP by pilot cars manned and equipped to handle spills.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Other legacy materials may be encountered during construction and operations. If encountered, these materials would be characterized to determine potential for reprocessing, reuse, or disposal.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>Small scale composting associated with organic materials generated at the worker housing facility may be incorporated within the centralized GMS in the Fiddle valley.</td>
<td>Hazardous Materials</td>
</tr>
<tr>
<td>An Explosives and Blasting Management Plan would be prepared for the SGP. Explosives storage, transport, handling, and use would comply with applicable Department of Homeland Security, Bureau of Alcohol, Tobacco, Firearms and Explosives, and MSHA regulations.</td>
<td>Health and Safety</td>
</tr>
<tr>
<td>For safety and security reasons, no alcohol, firearms, or illegal drugs would be permitted on site.</td>
<td>Health and Safety</td>
</tr>
<tr>
<td>For safety and security reasons, public access into the mine area would be prevented by using fencing, gate locking, security personnel, and/or notice postings that prohibit unauthorized entry; no unauthorized vehicles or personnel would be permitted on the SGP.</td>
<td>Health and Safety</td>
</tr>
<tr>
<td>Personnel transporting, handling, or using any hazardous chemicals (including sodium cyanide) would be trained to ensure the safe use of such materials. Perpetua would design, construct, and manage facilities to conform to ICMC.</td>
<td>Health and Safety, Fish, Wildlife, Hazardous Materials</td>
</tr>
<tr>
<td>Fuel and other petroleum products at the site would be stored in above ground containment structures, with appropriate secondary containment measures.</td>
<td>Health and Safety, Fish, Wildlife, Hazardous Materials</td>
</tr>
<tr>
<td>Air emissions, groundwater, surface water, and aquatic parameters would be monitored during mine construction, operation, closure, and post-closure as specified in the final authorizations from the regulating agencies.</td>
<td>Monitoring</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Monitoring would be conducted following the completion of closure and reclamation of all facilities and disturbance areas to demonstrate compliance with permit requirements and to measure the success of reclamation and mitigation.</td>
<td>Monitoring</td>
</tr>
<tr>
<td>The draft EMMP includes the following plans for monitoring aquatic resources: Stream and Wetlands Monitoring and Management Plan and Fisheries and Aquatic Habitat Monitoring and Management Plan.</td>
<td>Monitoring</td>
</tr>
<tr>
<td>The ore processing facility building would be enclosed.</td>
<td>Noise, Wildlife, Health and Safety</td>
</tr>
<tr>
<td>Appropriate sound dampening and muffling equipment would be utilized to minimize noise excursion from equipment and facilities. When possible, schedule high noise activities at the same time. Monitor and maintain equipment to reduce noise related impacts.</td>
<td>Noise, Wildlife, Health and Safety</td>
</tr>
<tr>
<td>When practicable, pumps, generators, and engines would be turned off when not in use to avoid unnecessary noise generation and reduce energy consumption.</td>
<td>Noise, Wildlife, Health and Safety</td>
</tr>
<tr>
<td>Electric line power would be utilized during operations to eliminate diesel generator noise, except in emergency situations when grid power is down or temporary use in remote areas where it is not practical to run power lines.</td>
<td>Noise, Wildlife, Health and Safety</td>
</tr>
<tr>
<td>An 8-mile temporary 16-foot-wide groomed OSV trail would be created adjacent to Johnson Creek Road between Landmark and Trout Creek Campground during construction of the Burntlog Route.</td>
<td>Recreation</td>
</tr>
<tr>
<td>A 16-foot-wide groomed OSV trail would be created south of Warm Lake Road to connect the southern end of Johnson Creek Road to the Landmark- Stanley Road. This 0.3-mile route would be used throughout construction and operations.</td>
<td>Recreation</td>
</tr>
<tr>
<td>During construction, approximately 13 miles of groomed OSV trail would be maintained along Cabin Creek Road (FR 467).</td>
<td>Recreation</td>
</tr>
<tr>
<td>Suitable surface coatings or exterior design features would be used on SGP buildings and other structures to reduce visual impacts.</td>
<td>Scenic Resources</td>
</tr>
<tr>
<td>Lighting would be managed within active mining areas to avoid unintended lighting of natural, wildlife usage areas. External lighting would be kept to the minimum required for safety and security purposes. Lights would be directed down toward the interior of the SGP and shielded, where appropriate.</td>
<td>Scenic Resources, Wildlife</td>
</tr>
<tr>
<td>Approximately 37% of the reclamation would be done concurrent to mining and ore processing; the remaining 63% would be accomplished during closure.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>The Yellow Pine pit would be backfilled with West End pit development rock during operations.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>A sinuous channel would be constructed through the backfilled area for the reconstructed East Fork SFSR with an average valley gradient approximating the historical, pre-disturbance river gradient.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>The backfill would be placed to achieve a mounded final reclamation surface to promote drainage away from the West End pit and prevent formation of a pit lake within Midnight pit.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>The floor of the sidehill pit southwest of the main West End pit would be graded to drain, covered with growth media, and revegetated.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Perpetua would begin with placement of soil/rock cover material, then construct wetlands and restore Meadow Creek and its tributaries within appropriately sized lined floodplain corridors, place growth media, and revegetate the area.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>Hangar Flats pit would be fully backfilled with development rock to the valley bottom elevation or slightly higher during mine operations. There would be no Hangar Flats pit lake.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Once all final mine closure/reclamation work has been completed, Perpetua would reduce the 21-foot-wide travel way of 19.8 miles of Burntlog Road (FR 447), 1.3 mile of Meadow Creek Lookout Road (FR 51290), and 2.0 miles along Thunder Mountain Road (FR 375) of Burntlog Route to their approximate pre-mining width.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>The approximately 15 miles of Burntlog Route connecting to Meadow Creek Lookout Road (FR 51290) and Thunder Mountain Road (FR 50375) would be decommissioned.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Following mining and ore processing operations, unless they are taken over by a third-party for ongoing use and maintenance, the Burntlog Maintenance Facility buildings would be removed. The sewer system and septic tanks for the facility would be decommissioned. Soil/rock beneath fuel storage areas and chemical storage buildings would be tested for contamination. All reagents, petroleum products, solvents, and other hazardous or toxic materials would be removed from the site and disposed of according to applicable state and federal regulations. After demolition of the buildings and facilities, the site would be graded, and drainage restored.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Perpetua would manufacture growth media material using screened fines from glacial till sources mined from the Yellow Pine pit, available mulched vegetation, and off-site composted material.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Planting, seeding, and mulching would be conducted in the fall and early winter to take advantage of snowpack and springtime moisture. Where cover crops are used in lieu of mulch, seeding would occur in the spring or fall followed by seeding of the permanent mixture.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Reclamation monitoring would begin during concurrent reclamation at SGP facilities. Quantitative and qualitative monitoring of reclamation success would begin the first growing season after final reclamation is completed and would continue until success criteria are satisfied.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Soil stability would be estimated for all reclaimed areas using qualitative descriptors.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Slope stability would be monitored during the erosion inspections.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>If the performance of reclaimed areas is not satisfactory, appropriate maintenance activities would be implemented. Maintenance activities may include one or more of the following: Sediment removal from sediment basins, stormwater drainage channels, and diversions as necessary to maintain their design capacity; Diverting surface water away from reclaimed areas where erosion jeopardizes attainment of reclamation standards; Stabilizing rills, gullies, and other erosion features or slope failures that have exposed development rock; Noxious weed and invasive plant species control; and, Re-seeding or re-applying reclamation treatments in areas where it is determined through monitoring and agency consultation that reclamation would not meet standards.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Perpetua would submit an annual report to the USFS and the other federal and state agencies that are responsible for issuing authorizations applicable to reclamation for the preceding calendar year. The annual report would contain descriptions of the reclamation activities completed during the previous year, a summary of areas reclaimed, a discussion of the results of the reclamation monitoring conducted, and corrective actions implemented.</td>
<td>Soils, Reclamation</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>A new 12-foot-wide gravel road would be constructed to provide public access from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375) through the SGP. During operations, the public access road would be used to travel through the SGP and would provide seasonal use, open to all vehicles. Vehicles passing through the SGP would be required to check-in with mine personnel at the North or South SGP entry points.</td>
<td>Transportation and Access, Health and Safety</td>
</tr>
<tr>
<td>Post reclamation, a road would be established over the backfilled Yellow Pine pit to allow public access through the reclaimed site and connect Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375). This would replace the operational phase public access route.</td>
<td>Transportation and Access</td>
</tr>
<tr>
<td>Prior to site preparation and construction of surface facilities, vegetation would be removed from operating areas. Merchantable timber on NFS surface lands could be purchased from the USFS. Non-merchantable trees, deadwood, shrubs, and slash would be removed, and any remaining vegetation would be grubbed using a bulldozer. The resulting material would be saved for future use in reclamation activities. Specifically, the organic matter would be chipped and stockpiled for use as mulch or blended to create a growth media additive. After vegetation removal, growth media would be salvaged and stockpiled. Stockpiles would be stabilized, seeded, and mulched to protect the stockpiles from wind and water erosion.</td>
<td>Vegetation</td>
</tr>
<tr>
<td>Perpetua would inspect and remove vegetation material (including noxious weeds) from mechanical equipment and properly dispose to minimize the spread of unwanted vegetation.</td>
<td>Vegetation</td>
</tr>
<tr>
<td>Wood wastes and wood mulch are the two primary sources of compost. Food waste produced from on-site meal preparation and wastes may provide another source. Combined and properly managed during composting, these materials would provide a source of organic matter to be blended into substrate materials suitable for mitigation.</td>
<td>Vegetation</td>
</tr>
<tr>
<td>Perpetua would be responsible for noxious weed control within areas disturbed by SGP activities.</td>
<td>Vegetation, Wildlife</td>
</tr>
<tr>
<td>Develop and employ planting plans for wildlife benefits (cover, forage, etc.) using approved seed mixes.</td>
<td>Vegetation, Wildlife</td>
</tr>
<tr>
<td>Perpetua would use aquatic safe herbicides during vegetation management activities and noxious weed control. Adhere to chemical label restrictions, federal/state rules on usage. Use proper equipment for chemical application by trained personnel.</td>
<td>Vegetation, Fish</td>
</tr>
<tr>
<td>Perpetua or its designated contractor(s) would perform long-term maintenance as necessary, including maintaining and monitoring the Mitigation Area (including stream and wetlands) in perpetuity once the final performance standards are met or until such responsibility is relinquished to an appropriate third party (Forest Service, etc.) as approved by the USACE.</td>
<td>Vegetation, Wetlands</td>
</tr>
<tr>
<td>Perpetua would plant stream reclamation reaches and wetland reclamation areas with native plant species that are present in PAB, PEM, PSS, and palustrine forested wetlands and riparian areas along streams throughout the Mitigation Area.</td>
<td>Vegetation, Wetlands</td>
</tr>
<tr>
<td>To address stream temperature, riparian planting widths along restored and enhanced stream reaches would be 18 feet wide on each stream bank where possible. Taller and denser vegetation such as spruce trees would be planted. Further, the creation of the lined Stibnite Lake, a feature similar in size to the present Yellow Pine pit lake, would replace the function of the existing Yellow Pine pit lake in buffering stream temperature extremes and reduce maximum stream temperatures in East Fork SFSR in and downstream of the SGP.</td>
<td>Vegetation, Wetlands, Surface Water, Reclamation</td>
</tr>
<tr>
<td>Pre-construction water management activities would include the installation of surface water management features and implementation of best management practices to reduce erosion and sediment delivery to streams. These water management features and best management practices could include sedimentation ponds; run-on water diversion ditches, trenches, and/or berms; runoff water collection ditches; silt fence; water bars; culverts; energy dissipation structures; terraces; and other features specified in construction permits.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>Stormwater runoff from undisturbed areas upslope of mine features in the major drainages would be captured in the stream diversion channels described above or in other channels that would direct runoff away from disturbed areas. Smaller-scale diversion channels or earthen berms would be used, where necessary, to divert stormwater around other mine infrastructure.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Stormwater drains, ditches, and stream channels would be protected against erosion through a combination of adequate dimension, appropriate gradient, riprap, fabric-encapsulated soil lifts, or other stabilization materials. Diversions would be sized for a peak flow recurrence interval appropriate to the risk level of the facility, in recognition of other water management measures and fail-safes in place (excess flood storage and freeboard in the TSF, etc.), and in accordance with regulatory standards.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Existing streams that run through areas proposed for mining related disturbance would be diverted to prevent generation of contact water or commingling of contact and non-contact water, keeping clean water clean; and to prevent flooding of mine facilities by runoff generated off site.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Groundwater pumped from the dewatering wells would be considered to be contact water and would be managed through forced evaporation or active water treatment when the volume of pumped water exceeds the ore processing facility demand.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Channel segments constructed over fill or excavated in permeable materials would be constructed over a geosynthetic liner to reduce seepage. A transition layer of sand/gravel followed by riprap or similar would be placed over the liner for erosion protection.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Secondary containment for pipelines would consist of an open geosynthetic-lined trench, pipe-in-pipe, or backfilled geomembrane-wrapped trench, depending on location, and the pipeline corridor would drain to one of two pipeline maintenance ponds – one at the truck shop and one at the ore processing facility.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>A lined tailings pipeline maintenance pond would be located at the ore processing facility, to which tailings and process water in the tailings distribution or water reclaim pipelines would drain by gravity during maintenance shutdowns or if there is a leak in either pipeline. The pond would typically be empty except during maintenance or unforeseen problems with the tailings pipeline, pumping system, or TSF. The pond is designed to contain the contents of the pipelines and the runoff from the pond and lined pipeline corridor from a 100-year, 24-hour storm event plus snowmelt.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Underdrain collection sumps and downgradient monitoring wells would be used for TSF leak detection.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Water treatment would continue until metal concentrations from each source have stabilized at levels that meet water quality standards for discharge.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>A truck wash facility would include an oil/water separation system and water treatment facilities to enable reuse of the wash water.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>During mine operations, summer low flows in perennial diversion channels around the TSF impoundment and buttress (Meadow Creek), Yellow Pine pit (Hennessy Creek and East Fork SFSR tunnel), and West End pit (West End Creek) would be piped underground as a mitigation measure to maintain cold stream temperatures.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Hennessy Creek flow would be disconnected from the current unlined ditch passing alongside the Northwest Bradley dumps.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>A liner would be installed under the Meadow Creek stream/floodplain corridor to minimize water seepage into the Hangar Flats pit or the pit dewatering well system, and to avoid potential pit wall instability or loss of stream habitat as a result of stream dewatering.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>The underdrain system would convey spring and seep flows beneath both facilities to a collection sump at the buttress toe where the flows would be monitored for water quality prior to release into the stream system or capture for use in the processing circuit or treatment prior to discharge, depending on water quality.</td>
<td>Water Resources</td>
</tr>
<tr>
<td>Crushed rock would be placed on SGP access roads as needed to provide a durable surface and limit sediment transport.</td>
<td>Water Resources, Fish, Soils</td>
</tr>
<tr>
<td>Road surfaces throughout the SGP would be stabilized and managed to minimize transport of sediment, dust, and other materials, especially near watercourses through appropriate road engineering, surface drainage, watering, and application of dust control binding agents (magnesium chloride, lignin sulfonate, etc.), roadside ditching, road-cut stabilization, road surface maintenance, appropriate speed limits, and by limiting traffic.</td>
<td>Water Resources, Fish, Soils</td>
</tr>
<tr>
<td>During operations, runoff generated from direct precipitation on the TSF would be retained in the TSF water pool for reclaim to the ore processing circuit.</td>
<td>Water Resources, Fish, Wildlife, Wetlands</td>
</tr>
<tr>
<td>Riparian fringe and floodplain wetlands would be established on the broad, gently sloping floodplains on both sides of the reclaimed stream channels.</td>
<td>Wetlands</td>
</tr>
<tr>
<td>Valley margin wetlands would only be established where there is an upgradient water source sufficient to produce enough saturation and near surface water tables for wetland conditions.</td>
<td>Wetlands</td>
</tr>
<tr>
<td>Wetland reclamation would begin after the end of mine construction, with the first reclaimed wetlands occurring in the Blowout Creek drainage. Additional reclamation would occur in and after operational year 3 and continue through operations to closure year 25.</td>
<td>Wetlands</td>
</tr>
<tr>
<td>Salvaged O and A horizon soils from wetland or hydric soils (seed bank materials over or in combination with mineral soils uplands and wetland subsoils (growth media) would be used to create wetland soil conditions.</td>
<td>Wetlands</td>
</tr>
<tr>
<td>During Burntlog Route and SGP haul road construction and use, Perpetua would install and maintain sediment control measures and devices, such as culverts, culvert inlet protection devices, ditching, silt fencing, straw wattles, straw bales, and sediment catch basins.</td>
<td>Wetlands, Fish, Wildlife</td>
</tr>
<tr>
<td>Erodible cut and fill slopes along roads would be mulched, hydro-seeded or have durable rock inlay material to minimize the potential for sediment generation.</td>
<td>Wetlands, Fish, Wildlife</td>
</tr>
<tr>
<td>During winter road maintenance, Perpetua would remove snow from the Burntlog Route and haul roads at the SGP and the temporary construction access Yellow Pine Route. Perpetua would avoid disposal of snow in riparian areas, wetlands, or areas where snowmelt might cause road damage or erosion during spring melt. Care would also be taken to dispose of collected snow, which may contain sand or gravel, in a manner that avoids impacts to nearby streams and rivers.</td>
<td>Wetlands, Fish, Wildlife</td>
</tr>
<tr>
<td>Perpetua would use coarse sand (with less than 20% fines) for winter sanding of the main access road and SGP haul roads in combination with a fine to medium gravel as needed, (approximately 1/4 - 5/8-inch sizing).</td>
<td>Wetlands, Fish, Wildlife</td>
</tr>
<tr>
<td>Perpetua would salvage and preserve the growth media and seedbank materials of wetlands and riparian areas that would be impacted by the SGP. These salvaged soils, containing native seed banks, would be used to aid in establishment of wetland and riparian vegetation in the stream and wetland reclamation areas.</td>
<td>Wetlands, Vegetation</td>
</tr>
<tr>
<td>Soil would be amended with additional compost and other sources of organic matter necessary to successfully reclaim wetlands at the SGP.</td>
<td>Wetlands, Vegetation</td>
</tr>
<tr>
<td>Perpetua would maintain a recycling program at the SGP.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Description</td>
<td>Resources Affected</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>In order to reduce attractants, during construction and operations, trash and other miscellaneous inert (non-hazardous) garbage would be contained in on-site wildlife-resistant containers and hauled to the Valley County waste transfer station for disposal. Used oils, solvents, grease, and antifreeze would be handled separately from normal trash and garbage. Good housekeeping practices would include minimizing loose trash, odors, and access for wildlife to trash storage or disposal areas and prompt removal of trash.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Implement an Avian Protection Plan at the SGP for transmission lines, including designing power lines and poles to minimize potential bird mortalities due to electrocution. Develop procedures for managing nests of protected species on utility structures (if nests are built).</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Construct and operate all overhead powerlines/transmission lines and related facilities in accordance with APLIC suggested practices (APLIC 2006) as described in Idaho Power’s Avian Protection Plan.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Electric power structures to serve the SGP facilities would be designed and constructed to avoid raptor perching on structures for predation purposes and minimize the risk of their being electrocuted.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would install a wildlife exclusion fence around the TSF, process facility areas, and related process ponds in order to reduce the potential for mortalities.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would plan routine inspections of TSF facilities for wildlife use. If needed, Perpetua would implement measures to remove wildlife and install additional BMPs to reduce wildlife exposure to these areas.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>If critical wildlife zones or corridors are identified, restricted or season access will be established prior to construction or expansion activities to the extent practicable. Physical barriers and/or signage will be added identifying these areas and site-specific measures will be implemented to minimize impacts.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would implement an animal trapping and relocation plan, as necessary, for nuisance species for safety of staff, visitors, and animals.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would install fences along and around the ore processing facilities, TSF, explosive storage areas, and composting/landfill, excluding pit perimeters and high walls.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would install signs of known wildlife crossing and usage areas along access and SGP haul road corridors and all active facility areas. Locations are yet to be determined but signs would be installed to state the road name and mile markers where these corridors are known to exist. These would also be referenced in the training materials.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would provide tiered training for awareness, sighting, operations and maintenance, and restoration. Cross training to include noxious weeds, maintenance needs, unsafe conditions, etc., as well as reporting mechanisms. All mine personnel and visitors would receive some level of training tiered appropriately based on where they are working, type of work activities, and reason for mine visit. Forms would be developed to document training and identify how often training needs to be refreshed. Fact sheets would be developed on known wildlife in the area including pictures, warnings, and what to do if encountered.</td>
<td>Wildlife</td>
</tr>
<tr>
<td>Perpetua would design and manage the TSF and associated facilities to reduce wildlife attraction. These include the following:</td>
<td>Wildlife</td>
</tr>
<tr>
<td>• Surface area of the supernatant pond would be minimized to the extent practical.</td>
<td></td>
</tr>
<tr>
<td>• Install an 8-foot fence around the TSF facility to exclude wildlife from the facility.</td>
<td></td>
</tr>
<tr>
<td>• Implement an avian mortality reporting system for the TSF and contact water ponds.</td>
<td></td>
</tr>
<tr>
<td>• Use skirting to enclose open spaces as necessary beneath raised structures as practical.</td>
<td></td>
</tr>
<tr>
<td>• Follow the ICMC to avoid features possibly attractive to wildlife, as feasible.</td>
<td></td>
</tr>
</tbody>
</table>
Erosion control techniques at the SGP would include mulching, wetland sodding; planting of vegetation to stabilize slopes; and use of silt fences, biofilters, brush mats, erosion control fabric, and/or fiber rolls along temporary swales, perimeter dikes, and stream banks. In addition, to minimize human disturbance, permanent signage would be posted around the perimeter of individual project sites to prohibit unauthorized foot traffic and the use of all-terrain vehicles and motorbikes, dumping, draining, and cutting and/or removal of plant materials.

Sumps would be constructed with at least one side having a shallow grade for wildlife egress. Sumps would be backfilled and reclaimed when no longer needed for drilling.

Mine site facilities would be monitored in accordance with the draft EMMP for the presence and potential mortality of birds, mammals, reptiles, and amphibians. Sightings of rare or sensitive wildlife, along with any wildlife mortalities, would be recorded and provided in periodic reports to the Forest Service, USFWS, and IDFG.

Perpetua would provide mine personnel with mobile deterrents to avoid conflicts with wildlife – sprays, air horns, etc.

Perpetua would establish and post speed limits for the Burntlog Route, SGP haul roads, and light vehicle access roads on the SGP site. Slower speed limits would be posted at known wildlife crossings and along defined migratory corridors during migration season.

There would be no hunting or discharge of firearms during construction and operations within the SGP area. The SGP site would be posted to prohibit hunting, and employees would be prohibited from carrying firearms on the SGP.

Perpetua would employ vegetation maintenance for safety along roads, removal of hazard trees, and riparian conservation areas, etc. – coordinate such that wildlife protection and restoration are incorporated during maintenance.

### 2.4.9.1 Agency Identified Mitigation

Once environmental impacts are identified and described, mitigation measures are considered. Mitigation measures required by the Forest Service would represent reasonable and effective means to reduce the impacts identified in the resource analysis or to reduce uncertainty regarding the forecasting of impacts into the future. If environmental impacts are inevitable, certain regulatory programs may require compensatory mitigation of the impacts. Any mitigation measures are in addition to the regulatory requirements ([Table 2.4-12](#)) and project design features ([Table 2.4-13](#)) accounted for in the impact analysis.

### 2.4.9.2 Stibnite Gold Mitigation Plan

The basis of the Perpetua’s proposed EDFs are impact avoidance and minimization up front or as part of operations. The potential impacts of the SGP remaining after applying the avoidance and minimization measures were addressed by Perpetua on a resource-basis by further avoidance, minimization, and/or compensatory mitigation described in proponent-proposed specific resource mitigation plans. The following mitigation plans have been developed for the SGP:

- Stibnite Gold EMMP (Brown and Caldwell 2021c);
Fisheries and Aquatic Resources Mitigation Plan (Brown and Caldwell, Rio Applied Science and Engineering, and BioAnalysts, Inc. 2021b);

Fishway Operations and Management Plan (Brown and Caldwell, McMillen Jacobs Associates, and BioAnalysts 2021a); and

Conceptual Stream and Wetland Mitigation Plan (Tetra Tech 2021b).

Below is a brief discussion of each of these accompanying resource-specific plans.

Following the Record of Decision, Perpetua would integrate all required Forest Service requirements and mitigation commitments into the current draft EMMP (Brown and Caldwell 2021c). This EMMP consists of a program framework and appendices containing component monitoring and management plans. Perpetua would use the EMMP to guide monitoring, document permit compliance, implement impact reduction procedures, and address adaptive management thresholds and responses where impacts and mitigation effectiveness carry substantial uncertainty.

**Fisheries and Aquatic Resources Mitigation Plan**

Perpetua’s FMP (Brown and Caldwell, McMillen Jacobs, and BioAnalysts 2021a) describes the measures that Perpetua has proposed to minimize adverse impacts on fisheries and aquatic resources, with particular attention to fish species listed as threatened under the ESA: Columbia River bull trout (*Salvelinus confluentus*), Snake River spring/summer Chinook salmon (*Oncorhynchus tshawytscha*), and Snake River Basin steelhead (*Oncorhynchus mykiss*). The FMP also addresses westslope cutthroat trout (*Oncorhynchus clarki lewisi*), considered a sensitive species by the Forest Service and IDFG, and other resident fish species.

The FMP actions would begin during construction and continue throughout mine operations and into closure and reclamation. It is focused on Chinook salmon, steelhead, bull trout, and Westslope cutthroat trout, but would also have benefits for other fish and aquatic species. The FMP includes water quality protection; fish protection, salvage, and relocation during diversions and dewatering activities; a process of protection and salvage for draining of the Yellow Pine pit; measures to avoid impacts during blasting; monitoring streamflow; restoring passage in stream channels with fish passage impediments; and monitoring of fish and aquatic biota. The FMP and its components continue to be refined in consultation with natural resource and regulatory agencies.

**Fishway Operations and Management Plan**

Perpetua has proposed a fishway for safe upstream and downstream passage of anadromous and migratory fish in the East Fork SFSR during construction and mine operations, to be part of the tunnel that diverts the East Fork SFSR around the Yellow Pine pit.

Perpetua’s FOMP (Brown and Caldwell, McMillen Jacobs Associates, and BioAnalysts, Inc. 2021a) outlines the operation of the fishway and monitoring for effective fish passage as well as an adaptive approach to provide for fish trap and haul operations as an alternative, using the same facilities. Fish protection measures for the East Fork SFSR tunnel and Yellow Pine pit dewatering are outlined as well, such as a temporary fish barrier downstream of the Yellow Pine pit during tunnel construction, carefully
sequenced dewatering of the Yellow Pine pit, and start of fishway operations (Brown and Caldwell, McMillen Jacobs, and BioAnalysts 2021b).

Measures to avoid and minimize impacts to fish habitat are detailed in the FMP and FOMP (Brown and Caldwell, Rio ASE, and BioAnalysts 2021b and Brown and Caldwell, McMillen Jacobs, and BioAnalysts 2021a). As listed above, these measures including the following:

- **Water quality protection** - measures designed on managing contact and non-contact water to maintain and improve water quality while supplying sufficient water for mining and ore processing. Diversions, ditches, and other mine facilities would be lined and/or water collected and treated to protect water quality. Riparian corridors would be restored and enhanced, and certain diversions piped, to reduce stream temperatures. Water treatment would continue during both operations and the post-closure phase.

- **Fish protection, salvage, and relocation during dewatering and diversions** - measures for screening or excluding of fish from diversion channels, water withdrawals, low-flow pipes, and the Yellow Pine pit dewatering to exclude and protect fish. Work windows have been developed based on fish periodicity to account for the different life stages of the targeted fish species. During diversions and dewatering activities in fish bearing streams, fish handling and salvage protection measures have been identified to safely isolate, collect, handle, and transport the fish.

- **Trap and haul protocols at the fishway (if needed)** - the primary goal is operating and maintaining the East Fork SFSR fishway during construction and operations and later in the mine life by restoring the East Fork SFSR stream channel over the backfilled Yellow Pine pit to provide permanent, volitional upstream and downstream fish passage and access to important stream habitats of the upper East Fork SFSR and portions of Meadow Creek. If fish aren't able to use the fishway during any period, trap and haul procedures have been developed to safely collect, handle, and move fish upstream of the fishway.

- **Avoidance measures during blasting activities** - measures to largely avoid or minimize the potential effects from blasting activities using appropriate setback distances from aquatic habitats to limit blast-related air overpressure and ground vibrations to harmless levels. Other additional blasting techniques can also be used to reduce these levels, and BMPs and site-specific modification of methods can further minimize or prevent damage to fish and the aquatic environment.

- **Monitoring streamflow** - activities for maintaining, to the extent practicable, appropriate streamflows and streamflow monitoring in natural or restored channels where fish are present.

- **Stream restoration and enhancement** - design elements for stream restoration and enhancement based on natural channel design principles intended to restore permanent fish passage at Yellow Pine pit, improve fish habitat site-wide for spawning and rearing salmonids, and provide a net ecological benefit relative to current conditions.

- **Restoring passage in stream channels** - removing existing passage barriers within the mine site to allow for fish movement between streams and areas of the mine site where access is currently blocked or impeded within the SGP footprint as well as along the Burntlog Route.
• Monitoring fish and aquatic biota - provide the data necessary to evaluate how the various mitigation and protection measures are implemented, and to assess the status and trends and ongoing effectiveness. To address the potential for variances in the outcome of these measures, an adaptive management approach is outlined that would provide the mechanism to modify or adjust these measures or approaches in response to monitoring and evaluation as well as new information or technologies that may become available over the more than 20 years of construction, mining, reclamation, and restoration.

**Conceptual Stream and Wetland Mitigation Plan**

Construction of the SGP would permanently impact wetlands and other WOTUS subject to regulation under Section 404 of the CWA and requires a Department of the Army (DA) permit pursuant to Section 404. Perpetua’s Conceptual Stream and Wetland Mitigation Plan (CMP) (Tetra Tech 2021b) provides detailed descriptions of proposed restoration, establishment, enhancement, and/or preservation of aquatic resources to compensate for unavoidable impacts to WOTUS associated with activities that would be authorized by a DA permit. The CMP is conceptual until the impact analysis is finalized and the USACE has determined all mitigation requirements. The conceptual mitigation plan does demonstrate the feasibility of achieving the amount and types of mitigation to offset the impacts in a manner consistent with the 2008 Mitigation Rule. The CMP provides detailed descriptions of proposed restoration, establishment, enhancement, and/or preservation of aquatic resources to compensate for unavoidable impacts to WOTUS associated with activities that would be authorized by a DA permit (Tetra Tech 2021b).

The CMP describes mitigation to address the requirements of the USACE and EPA under the Compensatory Mitigation for Losses of Aquatic Resources under CWA Section 404 (Final Rule). The CMP includes the 12 required elements of compensatory mitigation plans (33 CFR 332.4(c)/40 CFR 230.94(c)): objectives, maintenance plan, site selection, performance standards, site protection, monitoring requirements, baseline information, long-term management plan, determination of credits, adaptive management plan, mitigation work plan, and financial assurances.

The CMP would be revised through the FEIS and with the USACE Regulatory Division—Walla Walla District, Boise Field Office, in compliance with the CWA Section 404/DA permit, stream and wetland delineations and jurisdictional determinations, development of the stream functional assessment for USACE-approved stream functional analysis, wetland and stream credits and debits determinations, and compliance with USACE’s 404(b)(1) Guidelines (40 CFR Part 230).

**2.5 Johnson Creek Route Alternative**

**2.5.1 Overview**

The Johnson Creek Route Alternative was developed to avoid or reduce certain impacts to IRAs, sensitive plant species, and wetlands. In this alternative the Burntlog Route would not be constructed and used for primary access to the SGP. The Johnson Creek Route would be used not only during initial SGP construction but would also be used during the operations and closure/reclamation phases of the SGP as well.
Development of the Johnson Creek Route would entail 216.6 acres of new cut and fill activity (including borrow sources) along existing roadways that follow segments of Johnson Creek and East Fork SFSR to make those roadways usable for mine access during its lifespan. Improvements to the Johnson Creek Route would include road widening and straightening, as well as drainage and bridge improvements to the Johnson Creek Road portion of the Johnson Creek Route. The Stibnite Road portion of the Johnson Creek Route would be improved by straightening curves, adding retaining walls, and installing culverts. It would approach the village of Yellow Pine at the junction of Johnson Creek and Stibnite roads.

This section describes only the differences from the 2021 MMP that have been incorporated into the Johnson Creek Route Alternative. Under this alternative, all of the mining, ore processing, and development rock storage activities would be the same as described in the 2021 MMP. Previously approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue as well as the ASAOC activities. The modifications in the Johnson Creek Route Alternative are listed in Table 2.5-1 and include the rationale for inclusion of each component. The proposed facilities and access roads related to this alternative are shown on Figure 2.4-1 and Figure 2.5-1. Forest Service requirements and EDFs as described in Section 2.4.9 would apply to the Johnson Creek Route Alternative.

<table>
<thead>
<tr>
<th>Phase – Component/ Subcomponent</th>
<th>Facility or Process Change</th>
<th>Rationale for Inclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Construction/Operations/ Closure and Reclamation – Access Roads</td>
<td>The Johnson Creek Route would be the mine access route as well as the public access route.</td>
<td>Using the Johnson Creek Route for mine access could avoid impacts from construction of approximately 15 miles of new road for the Burntlog Route, including impacts to IRAs, whitebark pine (a proposed threatened plant species), and wetlands and riparian areas.</td>
</tr>
<tr>
<td>Construction/Operations/ Closure and Reclamation – Public Access</td>
<td>The Johnson Creek temporary groomed OSV Trail from Landmark to Trout Creek campground would be maintained through operations. The segment from Trout Creek to Wapiti Meadows would be closed from construction through Closure and Reclamation.</td>
<td>Keeping the temporary groomed OSV trail open during construction and operations would provide for public access each winter and connect to other OSV routes during construction and mine operation.</td>
</tr>
<tr>
<td>Operations – Utilities/Communication Towers and Repeater Sites</td>
<td>Cell tower/repeater sites construction within IRAs would be by helicopter.</td>
<td>Helicopter construction could reduce impacts to IRAs and whitebark pine (a proposed threatened plant species).</td>
</tr>
</tbody>
</table>

### 2.5.2 Land Management and Affected Areas

For the Johnson Creek Route Alternative, the estimated maximum land affected by component and land ownership is shown in Table 2.5-2.

¹ Affected acres for utilities include both existing utility corridors and access routes, some of which would be upgraded, and new utility corridors and access routes.

² Approximately 65 acres associated with surface exploration pads and temporary roads (SGP component) have unknown land ownership breakdown because the exact locations of these exploration areas are not yet known; however, these are included in the PNF SGP subtotal.

³ Subtotals may not add to totals due to rounding.

⁴ Approximately 9 acres of land listed under the PNF is administered by the PNF but is within the boundary of the Salmon Challis National Forest.
2.5.3 Phasing and Timeline
The upgrades to the Johnson Creek Route, particularly along portions of the Johnson Creek Road and Stibnite Road, would take longer. Construction at the SGP could not be completed until the Johnson Creek Route is sufficiently upgraded. Accordingly, if the Johnson Creek Route Alternative were selected, the overall construction timeframe would need to be extended by a minimum of 2 years relative to the 2021 MMP in order to upgrade the Johnson Creek Route and complete construction at the SGP. The time period for SGP operations and closure and reclamation phases would be unchanged, but the start of operations would be delayed in comparison to the 2021 MMP.

2.5.4 Site Preparation, Access, Infrastructure, and Mine Operations
Site preparation, access, and infrastructure, and mining activities under the Johnson Creek Route Alternative would be the same as under the 2021 MMP except for construction/operations of the Johnson Creek Route as described below.

2.5.4.1 Access Roads
Under this Alternative, the Johnson Creek Route would be improved and used to access the SGP through construction, operations, and closure and reclamation and would be the only route of ingress and egress for the SGP. Road widening and straightening, along with drainage and bridge improvements, would be required for the Johnson Creek Road (CR 10-413) portion of the Johnson Creek Route. The Stibnite Road (FR 50412) portion would be improved by straightening curves, constructing retaining walls, and installing 182 18-inch culverts and two 60-inch culverts. Rock blasting would be required in areas to accommodate increasing the road width. Mesh and anchors, retaining walls, and concrete barriers are anticipated to be necessary due to steep rock canyon topography to mitigate safety hazards. The Johnson Creek Route would take approximately twice as long to construct as the Burntlog Route as the level and pace of construction would be limited by space constraints and the need to maintain some level of access through the construction zone to allow for passage of equipment, materials, and laborers to the mine site. It would also require drilling and blasting of rock overhands. Approximately 1 mile of road through the village of Yellow Pine would be paved.

Construction of facilities at the SGP would be completed following upgrades to the Johnson Creek Route. Construction of improvements to the Johnson Creek Route would require approximately 4 years due to the nature of the topography and terrain and the inability to do construction from both ends simultaneously.

During construction, Johnson Creek Road would require periodic temporary road closures. To complete upgrades to the Stibnite Road, daily road closures would be required from 10 a.m. to 4 p.m. during a 3-year construction period to conduct the cut and fill activities required to straighten curves and install retaining walls.

2.5.4.2 Public Access
During construction and mine operations, the public would share the Johnson Creek Route with mine related traffic transporting personnel, materials, and supplies to the SGP. The access route around the Yellow Pine pit would provide public access, employee access, and delivery access of supplies and
equipment to the processing, warehouse, worker housing facility, and administration areas. Therefore, this road would need to accommodate heavy vehicles in addition to light vehicles.

This alternative would include constructing a road through the SGP to accommodate public access and delivery of mining materials and supplies. The road would be constructed around the Yellow Pine pit and into the SGP as shown on Figure 2.4-2. South of the Yellow Pine pit, the through-site public access road would follow an alignment similar to the 2021 MMP through-site access road. As such, it would pass under the mine haul road and continue southward, and southwest of the ore processing area, connecting with the Thunder Mountain Road and continuing toward the Worker Housing Facility before exiting the site area to the southeast. This portion of the access road would not be plowed in the winter per current county maintenance standards and would not be winter-season accessible to the public.

Under the Johnson Creek Route Alternative, the Johnson Creek groomed OSV trail would be on the west side of Johnson Creek Road from Landmark to Trout Creek campground during operations as described for 2021 MMP but the segment along Johnson Creek Road from Trout Creek campground to Wapiti Meadows would be closed from construction through closure and reclamation. Other OSV trails as described in Section 2.4.4.4 would be the same as the 2021 MMP.

2.5.4.3 Utilities

The transmission line upgrade and new construction would be the same as under the 2021 MMP. However, the two VHF repeater sites would be located along Johnson Creek Road; one VHF repeater site would be located off FR 410 at Deadhorse point and the other on the north end at Golden Gate Hill. Helicopters would be used to construct and maintain high frequency radio repeater and cell tower sites located within IRAs managed for Backcountry/Restoration. Other utilities would be the same as 2021 MMP.

2.5.4.4 Off-site Facilities

Under the Johnson Creek Route Alternative, the access road maintenance facility would be shifted to the west and located on approximately 3.5 acres of NFS land near the intersection of Warm Lake and Johnson Creek roads, it would be accessed via Warm Lake Road. It would be called the Landmark Maintenance Facility and would include the same components as displayed in Figure 2.4-8 for the Burntlog Maintenance Facility described in the 2021 MMP.

2.5.5 Closure and Reclamation

The improvements to the Johnson Creek Route would remain after mine operations end. Johnson Creek Road and Stibnite Road would not be returned to the pre-mine width. Rock cuts, 9-foot-high retaining walls, 182 18-inch culverts, and the two 60-inch culverts would remain.

Post-closure public access through the SGP would be the same as 2021 MMP (Figure 2.4-18).
2.6 Alternatives Considered but Eliminated from Further Detailed Study

Federal agencies are required under NEPA to rigorously explore and objectively evaluate a reasonable range of alternatives that could both meet the project purpose and need and potentially reduce environmental impacts from the project. The alternatives development and evaluation process also should briefly discuss the reasons for any alternatives eliminated from further analysis and thus, not developed in detail (40 CFR 1502.14). FSH 1909.15, Chapter 10, Section 14.4 provides further guidance on the evaluation and elimination of alternatives: “Alternatives not considered in detail may include, but are not limited to, those that fail to meet the purpose and need, are technologically infeasible or illegal, or would result in unreasonable environmental harm.”

The alternatives development process for the SGP was conducted in accordance with the Council on Environmental Quality (CEQ) and Forest Service regulations (40 CFR 1502.14 and 36 CFR 220.5, respectively) and Forest Service alternatives development guidance.

The component options that comprise the alternatives evaluated by the Forest Service and the cooperating agencies were focused on addressing one or more of the significant issues listed in Section 1.10, Issues.

Potential alternatives and component/subcomponent options were screened based upon four criteria:

- Does the alternative, including a combination of component options, meet the purpose and need of the project?
- Would the alternative or component option potentially reduce environmental effects to at least one resource?
- Is the alternative or component option technically feasible?
- Is the alternative or component option economically feasible?

If an alternative or component option would not have the potential to provide at least one environmental advantage as compared to the actions described in the 2021 MMP, it was eliminated from further study.

It should be noted that the emphasis for alternatives development is whether the alternative is reasonable, rather than whether the proponent or applicant likes or is itself capable of carrying out a particular alternative. Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant (46 FR 18026). Additional detail of the alternative development process and elimination of various options for detailed analysis is available in the Alternatives Development Report (AECOM 2020a).

2.6.1 Mining Method

Three potential types of mining method alternatives were examined and are detailed below.
**2.6.1.1 Underground Mining**

Under an underground mining alternative, ores from the Hangar Flats, Yellow Pine, and West End deposits would be mined via underground mining methods instead of open pits. Development rock generated from mining would be utilized to backfill completed underground workings for geotechnical stability or placed in surface facilities. The potential environmental benefit would be less surface disturbance for the mine operation.

In aggregate, grades for these three deposits above a 0.48 grams per ton (g/t) gold cut-off grade averaged 1.43 g/t gold, 1.91 g/t silver, and 0.064 percent antimony (M3 2021). Typical economic cutoff grades for underground mine operations are approximately 5 g/t gold. With gold grades well below typical economic cutoff grade, underground mining would not meet the purpose and need for the SGP to produce saleable minerals because doing so would not be an economic endeavor. Associated silver and antimony grades are not sufficient to offset the lower gold grade or to merit underground mining for production of those minerals.

In addition, underground mining development rock production would be insufficient to meet the construction needs for the SGP such as the TSF Embankment and Buttress. Therefore, this alternative would not completely remove the need for surface disturbance associated with mining the necessary construction materials. In addition, less development rock production could eliminate the currently proposed backfill and re-establishment of the East Fork SFSR across the Yellow Pine pit.

**2.6.1.2 West End Pit Backfill**

This alternative would involve placement of development rock in the West End pit during reclamation. Backfill of the West End pit would reduce or eliminate the post-reclamation West End pit lake and the amount of development rock placed in the TSF Buttress, Hangar Flats pit backfill, and Yellow Pine pit backfill.

Currently proposed project phasing enables backfilling of the Hangar Flats and Yellow Pine pits with development rock from the West End pit during operations. However, as the final pit is mined, backfill of the West End Pit could not be conducted safely until mining in that pit ceased. This would require re-handling and haulage of tens of millions of tons of development rock that would need to be placed temporarily in other locations back to the West End pit. The rehandling of development rock would increase the duration of mine operations to rehandle the development rock into the West End pit after mining in the pit ceased. This would increase mining equipment traffic and emissions over the life of the SGP.

Development rock from the West End pit is currently scheduled to be incorporated into the TSF Embankment and Buttress, and the backfills of the Hangar Flats, Midnight, and Yellow Pine pits. Rehandling the development rock required to backfill the West End pit would necessarily change the currently proposed final configuration of one or more of these other sites, potentially including reductions to the currently proposed pit backfills. Therefore, this alternative does not represent a net reduction of environmental effects. In addition, the operation costs associated with rehandling a large amount of development rock would negatively affect the economic feasibility of the SGP.
2.6.1.3 Electric Mining Equipment

Certain mining equipment, such as large shovels, drills, and haul trucks, can be powered with electricity and have been in some of the world's larger mine operations for years. There is a trend toward powering a wider variety of mining equipment with electricity. This reduces the need for diesel fuel handling and combustion at mine sites, reducing local air emissions. However, mining equipment of the type and moderate size proposed for use at the SGP is still typically powered by diesel engines, and this is what Perpetua has proposed for the SGP.

To constrain or dictate the selection of mine equipment is outside the purview of the PNF regulatory approval. Air impact analysis for the SGP has shown that regulatory limits related to the air emissions from the mining equipment fleet would be complied with so major reductions in equipment emissions is not required. Electrifying the proposed mining equipment would not reduce environmental impacts associated with ground disturbance, water management, geological hazards, hazardous materials, and associated resources.

2.6.2 Processing Method

Two potential types of processing method alternatives were examined and are discussed further below.

2.6.2.1 Off-Site Gold Processing

Under this alternative, raw ore would be processed off-site and would reduce the amount of reagents transported and used at the SGP, and the number of employees traveling to the site. It would also eliminate the need to store mill tailings at the SGP site. Transporting approximately 22,000 tons per day by trucks to an offsite mill would require approximately 550 round trips daily during the 15 years of mine operations. This would greatly increase the air emissions and transportation impacts of the SGP and dramatically increase operational costs. The main problem with this alternative is that there currently is no commercial milling operation in the U.S. West that could economically process the SGP ore. So, a new mill, with all the same associated environmental impacts as the proposed SGP on-site mill would need to be constructed.

In the absence of on-site ore processing, the environmental benefits of legacy material removal (e.g., SODA) to allow for construction of the on-site TSF would also not be realized.

2.6.2.2 Dry Stack Tailings

The proposed tailings management would involve deposition of a tailings slurry in the proposed TSF where the contained solids would settle out and the accumulated water would be recycled to the mill process. This type of tailings management requires careful attention to the handling of the water balance in the tailings system and the geotechnical stability of the embankment forming the TSF. There is also the potential for subsurface seepage of tailings water out of the bottom of the TSF. Alternative methods for handling tailings include: 1) dewatering the tailings mechanically and transporting the "dry" tailings solids to the TSF, and 2) partially dewatering the tailings to produce a paste which is then pumped to the TSF. These approaches eliminate or greatly reduce the amount of tailings water stored in the TSF reducing the concerns for water balance, subsurface leakage, and geotechnical stability of the tailings embankment.
The use of the dry stack method of tailings disposal was evaluated and determined to be technically and economically infeasible. The ore processing rate and tailings grind size are not conducive to the generation of dry tailings. In addition, although the "dry" tailings could be handled as a solid waste, they would still contain appreciable moisture and seasonal high precipitation and freezing temperatures could create day to day handling problems.

Paste tailings disposal was also evaluated and determined to be technically feasible but not economically feasible and did not offer environmental advantages over other action alternatives. Additional information on the evaluation of tailings disposal methodologies is included in the Technical Memorandum titled “Review of Midas Gold Tailing Technology for the Stibnite Gold Project and Alternatives, Valley County, Idaho” (AECOM 2020b).

2.6.3 Facility Locations

Alternative locations for four project facilities were examined and discussed further below.

2.6.3.1 Tailings Storage Facility

Several options were considered for the TSF component. These included:

- Construction of the TSF in a series of smaller facilities separated by TSF embankments in a phased manner;
- Construction of the TSF within the East Fork SFSR valley upstream of Fern Creek; and
- Construction of the TSF in the East Fork SFSR east of Meadow Creek in areas previously undisturbed by mining.

The TSF location in the East Fork SFSR east of Meadow Creek was fully analyzed as Alternative 3 in the DEIS (Forest Service 2020a). There were no environmental benefits noted for this location. Therefore, detailed analysis of this location was not retained for the SDEIS.

The construction and use of multiple, phased TSF locations would increase the disturbance footprint, triple the number of TSF embankments, and the quantity of embankment construction material required for tailings storage. Therefore, there would be an increase of impacts to soils, water resources, and aquatic resources under this scenario, resulting in no reduction to environmental effects.

The TSF location within the East Fork SFSR upstream of Fern Creek would not realize the benefit of legacy material removal from Meadow Creek and would increase effects on water resources plus fish and wildlife habitats by increasing ground disturbance (approximately 510 acres).

2.6.3.2 Power Transmission Line Route

Two potential transmission line route alternatives were considered:

- Locating the transmission line segment from the Johnson Creek substation to the mine on the north side of the TSF, following a former jeep trail alignment between the Horse Heaven and Meadow Creek IRAs; and
Extending the existing 138-kV transmission line from the Yellow Pine substation to FR 458 east of Golden Hill road and then along Stibnite Road (FR 50412) to the SGP.

These route options did not reduce environmental effects of the SGP as they would require additional disturbance for access and maintenance to install longer routes; further, topographical constraints could require use of self-supported steel structures rather than conventional wood poles. In particular, the Horse Heaven to Meadow Creek route was analyzed as part of Alternative 3 in the DEIS (Forest Service 2020a). Based on that analysis indicating it would have greater impacts on IRAs, riparian and wetlands habitat, and associated wildlife, it was not retained for detailed analysis in this SDEIS.

In addition to environmental effects, the Stibnite Road route has relatively more exposure to avalanche hazards.

### 2.6.3.3 Worker Housing Facility

Under this alternative, the worker housing facility would be located within the mine area. Architectural and engineering controls would be utilized to reduce interior noise along with sound control building materials.

This location was evaluated under Alternative 3 of the DEIS (Forest Service 2020a). There was no reduction in environmental effects associated with this location plus it moved the housing facility into an area of greater geological hazard risk. Therefore, it was not retained for detailed analysis in this SDEIS.

### 2.6.4 Transportation and Access Road Alternatives

Six potential transportation and access road component options were examined and are discussed below.

#### 2.6.4.1 South Fork Route

Under this alternative, the South Fork Route would serve as the main access road, utilizing Warm Lake Road, South Fork Road, East Fork SF SR Road, and then Stibnite Road, for SGP access. This route was determined to have greater environmental impacts and greater safety issues than other alternatives; therefore, it was not technically feasible, did not reduce environmental effects, and was not carried forward for further evaluation.

#### 2.6.4.2 Lick Creek Route

Under this alternative, the Lick Creek Route would serve as the main access road, utilizing Lick Creek Road from SH 55 to East Fork SFSR Road, and then Stibnite Road, for SGP access. This route met the purpose and need; however, it would not lessen potential environmental impacts and posed greater safety issues than other alternatives. This route was determined to not be technically feasible, did not reduce environmental effects, and was not carried forward for further evaluation.

Other alternative road segments were also considered that could be combined with others to provide access to the SGP including Cabin/Trout Creek Road, Old Thunder Mountain Road, and Riordan Creek Road. These segments were eliminated because they did not lessen potential environmental impacts, posed greater safety issues (Old Thunder Mountain Road), and were economically not feasible.
2.6.4.3 Convoy Mine Traffic

Under this alternative, all mine workforce, supply and haulage, and miscellaneous traffic would be transported in convoys (grouping deliveries together) of approximately six vehicles during construction and operations. Convoys would be used to minimize disruption to the public and would be used Monday through Friday from approximately 6:00 a.m. to 8:00 p.m. Convoys could improve public safety and reduce the risk of traffic accidents.

This alternative would not reduce the overall volume of traffic to and from the SGP. Recreational or public vehicles using the same route as the convoys would still encounter mine related traffic. Oncoming vehicles would have to wait for the convoy to pass before entering the roadway, while vehicles behind the convoy would be required to follow along until a safe (longer) place to pass was available. Designated pullouts or turnouts for the convoy to allow safe passage of following vehicles would help mitigate traffic related concerns. However, because convoys would not reduce the volume of traffic, there would be no discernable environmental advantages. Additionally, coordinating arrival and delivery times of all vendors traveling to the SGP could prove technically infeasible. Therefore, this alternative was not carried forward for further evaluation.

2.6.4.4 Public Parking Lots at Project Components

This alternative would involve development of public parking lots for recreational use at the worker housing facility and/or Knox Ranch near Cascade, Idaho. It would also include accommodations for snowmobile trail grooming by either constructing a storage shed for grooming equipment at the parking lot or hauling grooming equipment from Cascade to the lot.

Parking lots in mine areas increase the potential impacts associated with public safety and geological hazards. They also lead to potential inconsistencies between the regulatory agencies’ independent responsibilities to regulate mining and public access. Therefore, they were not evaluated further.

2.6.4.5 No Temporary OSV Trail

In this alternative, the proposed temporary OSV trail would not be developed. Instead, wintertime traffic would be diverted to the South Fork Route. The rationale for eliminating the South Fork Route from further evaluation is described in Section 2.6.4.1. Without diversion of wintertime traffic, electing to not develop a temporary trail would increase SGP impacts to recreational use.

2.6.5 Water Management Alternatives

Four potential component options for water management were examined and are discussed below.

2.6.5.1 Dry Mining and Processing

The ability to mine and process ore under dry conditions was examined and determined to be technically infeasible. However, pit dewatering is necessary to meet the purpose and need for the SGP because the targeted minerals reside primarily below the water table. There are no technically feasible dry processing methods for the beneficiation of gold and silver from ores exhibiting the mineralization type present at the SGP.
2.6.5.2 West End Pit Drainage

For this alternative, an engineered drain utilizing a head gate to a pipe would be installed at the base of the West End pit to convey water from the pit bottom to West End Creek. This would prevent the formation of a pit lake in West End pit but would not reduce effects on water chemistry in the pit because groundwater and meteoric water entering the pit would still interact with the exposed pit walls. In addition, long-term operation and maintenance of the gate and pipe would be susceptible to technical feasibility issues similar to the historical mine diversion and drainage features at the SGP.

2.6.5.3 Modified Blowout Creek Restoration

Under this modification, a French drain design would not be used to control water and sediment conveyance at the Blowout Creek drainage. Instead, the drainage slopes would be graded to improve their hydrologic functioning condition. This alternative was not evaluated further because it did not result in a reduction of environmental impacts from the 2021 MMP.

2.6.5.4 Yellow Pine Pit Diversion without Fish Passage

For this alternative, the diversion of the East Fork SFSR around the Yellow Pine pit area would not accommodate fish passage. This alternative was examined as part of Alternative 3 in the DEIS (Forest Service 2020a). It is not evaluated further because it did not result in a reduction of environmental impacts.

2.7 Agency Preferred Alternative

Following their review of the environmental impacts as discussed in the SDEIS, the Forest Service has identified the 2021 MMP as their Preferred Alternative for the SGP because this alternative:

- Incorporates water management and closure activities to reduce the duration of long-term water treatment requirements.

- Incorporates measures to manage stream temperatures.

- Reduces the geotechnical stability, hazardous materials transport, and public health and safety transportation risks during operations (2021 MMP: 26 landslides/rockfalls and 38 avalanche paths versus Johnson Creek Route Alternative: 45 landslides/rockfalls and 94 avalanche paths).

- Reduces potential for spill contamination, sedimentation, and turbidity to streams during operations (2021 MMP: 9 miles of travelway within 0.5 miles of streams, 37 stream crossings, 1.6 miles of travelway within 100 feet of streams versus Johnson Creek Route Alternative: 27 miles of travelway within 0.5 mile of streams, 43 stream crossings, and 6.5 miles of travelway within 100 feet of streams).

- Reduces acres of riparian area lost within off-site focus area (2021 MMP: 299.5 acres versus Johnson Creek Route Alternative: 352.6 acres).
• Reduces the volume of timber resources removed (2021 MMP: 595 acres versus Johnson Creek Route Alternative: 733 acres), as well as acres of timberland permanently converted to non-productive land use (2021 MMP: 66 acres versus Johnson Creek Route Alternative: 282 acres).

• Reduces public safety risks and potential accidents during operations (Johnson Creek Route Alternative has steeper topography and terrain requiring wider roads, more cut/fill sections and more switchbacks; traffic including heavy equipment would be routed through the village of Yellow Pine for the duration of the SGP; general public would utilize same roads as large mining equipment).

• Reduces potential impacts such as access to tribal fisheries restoration activities along Johnson Creek Road during operations.

The Agency Preferred Alternative would reasonably accomplish the purpose and need for the federal action, while giving consideration to environmental, economic, and technical factors.

2.8 Summary Comparison of Alternatives

Table 2.8-1 provides a tabular summary and comparison of impacts from the components of the No Action Alternative, the 2021 MMP, and the Johnson Creek Route Alternative. A comparison of the 2021 MMP to earlier proposed plans can be found in Perpetua 2021a (Table A-1).
This page left blank intentionally.
### Table 2.8-1 Alternative Comparison and Impact Summary

<table>
<thead>
<tr>
<th>Issue</th>
<th>Indicator</th>
<th>Baseline Conditions</th>
<th>No Action Alternative</th>
<th>2021 MMP</th>
<th>Johnson Creek Route Alternative</th>

<tbody>
<tr>
<td>Minerals present at the site are economically valuable</td>
<td>Amount of ore extracted</td>
<td>132.3 M tons of measured and indicated ore (including tailings)</td>
<td>Same as Baseline Condition.</td>
<td>112 M tons of ore would be mined. About 3.2 M tons of historical Bradley tailings would also be removed and reprocessed. Total ore processed would be 115.2 M tons.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Minerals contribution to national economy</td>
<td>Depletion of mineral resources</td>
<td>Mineral reserve is approximately 4.819 M oz ounces of gold, 6.431 M oz of silver, and 148.686 M lbs. of antimony</td>
<td>Same as Baseline Condition.</td>
<td>Recover, over 15 years of mill production, 4.238 M oz of gold, 1.710 M oz of silver, and 115.342 M lbs. of antimony.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Change in topography</td>
<td>Alteration of topography</td>
<td>Legacy pit highwalls undisturbed valley bottom</td>
<td>Same as Baseline Condition.</td>
<td>Three new open pits, backfilled but highwalls remaining, TSF and TSF buttress in valley bottom, road cuts/fills along access roads.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Geotechnical stability</td>
<td>Stability of selected locations</td>
<td>Rockfalls, landslides and avalanche paths</td>
<td>Same as Baseline Condition.</td>
<td>26 landslides and rockfalls along access road route 38 avalanche paths along access road route. 45 landslides and rockfalls along access road route.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Geotechnical stability</td>
<td>Long-term geologic/geotechnical stability of TSF</td>
<td>No TSF present.</td>
<td>Same as Baseline Condition.</td>
<td>Underlying bedrock is more than sufficiently competent to support the TSF (rock types consist of quartz monzonite, diorite, granite and rhyolite). Designed to meet regulatory stability criteria even in the absence of the downstream buttressing provided by the TSF Buttress.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>Geographical extent of pollutant concentrations and deposition.</td>
<td>No SGP air emissions to affect existing conditions</td>
<td>Same as Baseline Condition.</td>
<td>SGP air quality impacts would be less than the National Ambient Air Quality Standards (NAAQS) because emissions are below deposition significance levels.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>Type and volume of air pollutants emitted, including haze precursors, airborne dust, and HAPs.</td>
<td>No SGP air emissions to affect existing conditions</td>
<td>Same as Baseline Condition.</td>
<td>Emission inventories for construction through LOM Year 18 indicated that the peak year for aggregated pollutant emissions would be LOM Year 10, also the peak year for mine throughput.</td>
<td>Same as 2021 MMP, except for those changes due to emissions location due to use of Johnson Creek Route (i.e., different haul routes).</td>
</tr>
<tr>
<td>Air Quality</td>
<td>Criteria air pollutant ambient concentrations outside the Operations Area Boundary anywhere the public is allowed unrestricted access.</td>
<td>Current air quality in the SGP area is good, and in attainment with air quality standards.</td>
<td>Same as Baseline Condition.</td>
<td>SGP air quality impacts would be less than NAAQS because and below deposition significance levels.</td>
<td>Same as 2021 MMP, except that locations of off-site concentrations may differ due use of Johnson Creek Route rather than Burntlog Route.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>Comparison of modeled concentrations to Class I and Class II increments.</td>
<td>Current air quality in the SGP area is good, and in attainment with air quality standards.</td>
<td>Same as Baseline Condition.</td>
<td>SGP air quality impacts would be less than the Class I and Class II increments.</td>
<td>Same as 2021 MMP, except that magnitude and locations of off-site concentrations may differ due use of Johnson Creek Route rather than Burntlog route.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>HAPs (including Hg emissions and Hg deposition).</td>
<td>Background concentrations and deposition occurs due to transport from distant industrial and urban sources.</td>
<td>Same as Baseline Condition.</td>
<td>Emissions HAPs, HCN, and Hg estimated for peak mine production year. Deposition of Hg limited in extent and well below health-based thresholds. HAP emission impacts are less than state acceptable ambient non-carcinogenic concentrations/acceptable ambient carcinogenic concentrations (AAC/AACCs).</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>

<td>---------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>The SGP may affect air quality characteristics and resources</td>
<td>Deposition impacts from nitrogen and sulfur compounds at Class I areas and specified Class II wilderness areas.</td>
<td>Existing deposition rates occur due to transport from distant industrial and urban sources.</td>
<td>Same as Baseline Condition.</td>
<td>Modeling of N and S deposition in areas of concern show that deposition rates are below acceptable levels for Class I areas.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>The SGP may affect air quality characteristics and resources</td>
<td>Near-field plume blight and far-field regional haze impacts in protected areas.</td>
<td>No SGP sources to create visible near-field plumes. Existing regional haze occurs due to transport from distant industrial and urban sources.</td>
<td>Same as Baseline Condition.</td>
<td>SGP sources may cause visible plumes at the closest Class II wilderness area (FCRNRW) for a small fraction of daylight hours (~0.02 hours). Far-field modeling of regional haze shows contribution from SGP sources would be below federal significance level.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>The SGP activities could contribute to factors that influence climate change.</td>
<td>GHG emissions from SGP activities (construction, operations, and closure and reclamation), expressed as MT of CO2e of GHGs.</td>
<td>No emissions.</td>
<td>Same as Baseline Condition.</td>
<td>Maximum LOM 3 200,671 MT (221,201 short tons/yr.) of CO2e of total annual GHG emissions.</td>
<td>Small incremental differences from the 2021 MMP. GHG emissions would be reduced because the Burntlog Route would not be constructed; however, the construction activities required on the Johnson Creek Route would likely offset the decrease and would likely end up very similar.</td>
</tr>
<tr>
<td>Changing climatic conditions, in synergy with the SGP (including construction, operations, and closure and reclamation), could impact the physical, biological, and social resources.</td>
<td>Changes in hydrologic patterns (drought, precipitation variability and seasonality). Changes in temperature (extreme heat/cold, or overall change in annual or seasonal temperatures). Changes in extreme weather events (flash flooding, wildfires, severe storms).</td>
<td>Current trends show variable annual average precipitation and drought patterns, decreases in snowpack, and decreases in streamflow. Current trends show increases in annual average temperature and more frequent temperature extremes. Current trends show increased frequency and intensity of extreme weather events.</td>
<td>Same as Baseline Condition.</td>
<td>Changing climatic conditions would be expected to result in decreased soil moisture and quality; air quality; annual streamflow; groundwater recharge; water quality; increased surface water temperatures; increased spread of insects and diseases; changes in the timing, duration, and severity of fire seasons; and habitat loss and fragmentation.</td>
<td>Same as 2021 MMP, except the severity of climate change impacts may be reduced for surface water (quality and quantity), wetlands and riparian resources, vegetation (including general vegetation communities, botanical resources, and non-native plants), fish resources and fish habitat, wildlife and wildlife habitat, and special designations.</td>
</tr>
<tr>
<td>The SGP may result in long-term adverse impacts to soil resources.</td>
<td>Acres and proportion of TSRC activity area that are converted from a productive site to a non-productive site (TSRC, as defined in the Payette Forest Plan). Acres and proportion of DD activity area that have altered soil characteristics resulting in loss of productivity and altered soil-hydrologic conditions.</td>
<td>TSRC Existing conditions of TSRC in the PNF activity area is approximately 259 acres within the combined subwatershed activity areas (7,468 acres), or roughly 3 percent. Existing conditions of TSRC in the BNF activity area is approximately 904 acres of the combined subwatershed activity areas (76,196 acres), or roughly 1 percent. DD Existing conditions of DD within the transmission line ROW is estimated at 8 percent.</td>
<td>Same as Baseline Condition.</td>
<td>TSRC PNF Activity Area The magnitude of impacts to soil resources within the PNF activity area includes excavation, grading, or filling of up to 1,457 acres (approximately 120 acres of which are already disturbed to some degree from historical mining activities or other TSRC). This results in a net increase of TSRC in the PNF activity area of approximately 1,198 acres (from an existing 259 acres to 1,457 acres). Overall TSRC under 2021 MMP would increase from approximately 3 percent to 17 percent of the PNF activity area. TSRC BNF Activity Area The magnitude of impacts to soil resources within the BNF activity area includes excavation, grading, or filling of up to 902 acres (approximately 66 acres of which are already disturbed due to overlap with and use of existing dedicated roadways, etc.) This results in a net increase of TSRC in the BNF activity area of approximately 836 acres (from 904 acres to 1,740 acres). Overall TSRC under 2021 MMP would increase to 2 percent of the BNF activity area.</td>
<td>TSRC PNF Activity Area The magnitude of impacts to soil resources within the PNF activity area includes excavation, grading, or filling of up to 1,457 acres (approximately 120 acres of which are already disturbed to some degree from historical mining activities or other TSRC). This results in a net increase of TSRC in the PNF activity area of approximately 1,198 acres (from an existing 259 acres to 1,457 acres). <td>-----------------------</td>
<td>----------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>DD</td>
<td>The DD activity area is the area within the transmission line ROW that would be subject to vegetation clearing only and is estimated at up to 500 acres. The magnitude of impacts from vegetation clearing potentially include detrimental soil displacement, compaction and puddling on up to a conservatively estimated 75 acres (15 percent) within the ROW.</td>
<td>Same as Baseline Condition.</td>
<td>A total of 1,658,000 BCY of GM and seed bank material (SBM) would be required to meet the specified reclamation areas and GM/SBM thicknesses. Soil salvage would generate approximately 860,000 BCY of GM/SBM. The 797,702 BCY deficit of RCM would be generated from unsuitable unconsolidated till mined from the Yellow Pine Pit plus other cover material at the project site and amended for suitability. The quality of RCM would vary based on its source, the best material coming largely from the organic and alluvial soils of the Meadow Creek valley. Most of this material would be used for GM and SBM for wetland restoration. GM used for upland reclamation sites would mostly come from relatively poor upland soils. Overall, the majority of GM used would rate as poor or fair (per suitability criteria), due primarily to texture and coarse fragment content (Tetra Tech 2019a, 2021b). Additionally, the naturally high background levels of trace metals at the SGP represents a challenge for reclamation-related revegetation efforts. Perpetua’s proposed 3,000-ppm arsenic limit for suitable root zone material is high; however, the Forest Service also would require limits on the GM (that would overlay the root zone material) for arsenic, mercury, and antimony, and would require a screening of soils as well as laboratory testing.</td>
<td>Essentially the same as the 2021 MMP for the mining area, with disturbance footprint-related adjustments for required GM/SBM and GM deficit. No potential Burntlog Route surplus salvage to compensate for the GM deficit at the mine site.</td>
<td></td>
</tr>
<tr>
<td>BNF Activity Area</td>
<td>The magnitude of impacts to soil resources within the BNF activity area includes excavation, grading, or filling of 321 acres (approximately 133 acres of which are already disturbed due to overlap with and use of existing dedicated roadways, etc.) This results in a net increase of TSRC in the BNF activity area of approximately 188 acres (from 904 acres to 1,092 acres). Overall TSRC under the Johnson Creek Route Alternative would increase to 2 percent of the BNF activity area.</td>
<td></td>
<td></td>

<tr>
<td>DD</td>
<td>Essentially the same as the 2021 MMP (15 percent of ROW).</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Available RCM may not be of sufficient quantity or quality to achieve reclamation objectives of returning disturbed areas to productive conditions that sustain long-term wildlife, fisheries, land, and water resources.</td>
<td>Volume of RCM available for reclamation compared to expected demand to achieve reclamation objectives. Quality and suitability of RCM available for reclamation.</td>
<td>RCM availability is based on soil type, subsurface and bedrock character and topography in previously undisturbed areas within the SGP area.</td>
<td>Same as Baseline Condition.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Noise</td>
<td>The SGP may cause disturbance to NSRs (such as occupied residences and campgrounds).</td>
<td>Area affected by noise that exceeds Outdoor Ambient Sound Level and 55 dBA.</td>
<td>Baseline ambient sound levels vary by location and range between 34 and 64 dBA, L_{eq} over the 12 identified NSRs as summarized Table 3.6-2.</td>
<td>Same as Baseline Condition.</td>
<td></td>
</tr>
</tbody>
</table>

**Noise**

- Site 2 would have temporary impacts while transmission line work is within approximately 800-850 feet. There are no other source impacts at Site 2 due to distance.
- Construction: Temporary impacts at Site 2, Site 9, Site 10 and Site 11 while transmission line work is within approximately 800-850 feet. Site 10 and some parts of the FCRNRW
Issue Indicator Baseline Conditions No Action Alternative 2021 MMP Johnson Creek Route Alternative

Site 3 would have short-term, negligible, localized impact during construction, mainly caused by the Burntlog Route construction.
Site 5 would have a temporary increase in noise levels due to the Burntlog Route access road construction. Burntlog Maintenance facilities construction, and SGP-related traffic on Johnson Creek Route would cause the majority of noise impacts. The transmission line work would cause temporary impacts within approximately 800-850 feet.
Sites 6, 7, and 8 would have short-term, negligible, localized impacts caused by the transmission line upgrades.
Site 9 would have temporary impacts during transmission line is occurring. Include the utility access roads and facility construction at SGLF.
Site 10 would have short-term, negligible, localized impact caused mainly by SGP-related traffic on Johnson Creek Route access road.
Site 11 would have temporary impacts during the construction of the transmission line upgrades, including the utility access roads in the immediate vicinity, and SGP-related traffic on Johnson Creek Road.
Site 12 would have the highest impacts during the first year of Burntlog Route construction. The impacts at Site 12 would be short-term, negligible to minor, and localized.

Operations:
SGP-related traffic during operations would cause minor, long-term, and localized impacts from SH 55 to SGLF, and from SGLF to SGP or Burntlog Route. The borrow area impacts would be negligible to minor, long-term, but intermittent, and localized.
Utilities and off-site facilities would cause minor, long-term, and localized impacts.
Site 2 would have no impact.
Site 3 would have negligible impacts during Burntlog Route access road maintenance.
Site 5 would have negligible to minor, long-term impacts during road maintenance activities.
Sites 6, 7, 8, 9, 10, 11, and 12 would have negligible impacts during operations, with and without blasting.
Site 7 would have an increased impact during winter maintenance on Burntlog Route, remaining below 55 dBA. Substation noise is the only SGP-related noise impact at Sites 8, 9, 10, and 11.
Closure:
Temporary impacts at Site 5 while access road decommissioning work is within approximately 0.5 miles. No decommissioning-related noise of the transmission line into the SGP.

Site 3 would have negligible impacts during Burntlog Route access road maintenance.
Site 5 would have negligible to minor, long-term impacts during road maintenance activity due to use of Johnson Creek Route. There would be increased noise at Site 5 due to location of maintenance facility at Landmark.
Closure:
No impacts above recommended noise level. Johnson Creek Route would not be decommissioned and would remain as built.

<td>The SGP may cause accidental release of hazardous materials or wastes, including milling reagents and reaction products, during the transport, use, storage, and disposal of materials.</td>
<td>Volumes and types of hazardous materials and hazardous wastes transported, used, and stored during site operation.</td>
<td>Petroleum products are currently stored at existing facilities for the exploration activities. Fuel storage areas are present in 16 locations with capacities from 55 to 10,000 gallons.</td>
<td>Same as Baseline Condition.</td>
<td>Hazardous materials and petroleum products storage would be stored at the following locations: SGLF, Burntlog Maintenance Facility, Worker Housing Facility, and Fuel and Explosive Storage. Approximate hazardous materials annual use and transport volumes would include: explosives (7,400 tons), fuels and lubricants (6.6 million gallons); antifreeze (40,000 gallons); propane (2 million gallons); antimony concentrate (365 to 730 truckloads); sodium cyanide (4,000 tons); copper sulfate (1,250 tons); nitric acid (65,000 gallons); sulfuric acid (12,000 gallons) solvents (1,000 gallons) along with other chemicals as listed in Table 4.7-1.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Practices for storage and use on site including primary and secondary containment types and volumes and material handling practices.</td>
<td>Hazardous materials are used and stored on site in accordance with applicable regulations including secondary containment for fuels and other hazardous materials. Perpetua has developed documents for use and storage including a SPCC Plan and a Solid Waste Management Plan, which addresses management of hazardous materials.</td>
<td>Same as Baseline Condition.</td>
<td>Hazardous materials would be used and stored on site in accordance with applicable regulations including secondary containment for fuels and other hazardous materials. Perpetua would develop documents for use and storage including a SPCC Plan and a Solid and Hazardous Materials Handling and Emergency Response Plan, which addresses management of hazardous materials. Following regulatory requirements and plans for spill containment, control, and response would reduce the potential for spills and for impacts associated with those spills.</td>
<td>Same as Baseline Condition.</td>
<td>Same as Baseline Condition.</td>
</tr>
<tr>
<td>Hazardous materials transport traffic volumes during construction, operations, and closure and reclamation.</td>
<td>Petroleum products are transported to the site on an as-needed basis.</td>
<td>Same as Baseline Condition.</td>
<td>Overall heavy vehicle traffic between the SGLF to SGP, of which hazardous materials transport would be a part, would be approximately 45 trips per day as an AADT count for construction; for operations, the heavy vehicle AADT would be 33 daily trips; and for closure and reclamation the AADT would be 15 daily trips. These trips represent the risk of a traffic accident.</td>
<td>Overall heavy vehicle traffic between the SGLF to SGP, of which hazardous materials transport would be a part, would be approximately 45 trips per day as an AADT count for construction; for operations, the heavy vehicle AADT would be 33 daily trips; and for closure and reclamation the AADT would be 15 daily trips. These trips represent the risk of a traffic accident.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Travel route road hazards.</td>
<td>The existing routes are a combination of paved routes (Warm Lake Road) and existing native surface roads. There are potential road hazards along the routes used for delivery of supplies for the exploration project including landslide and rockslide areas, avalanche paths and routes close to streams. These would represent a potential for hazard for accidents and spills.</td>
<td>Same as Baseline Condition.</td>
<td>Burntlog Route has 26 landslide/ rockslide areas and 38 avalanche paths. Nine miles of the travel way have streams within 0.5 mile. The route crosses 37 streams.</td>
<td>Johnson Creek Route has potential road hazards, including 45 landslide or rockfall areas and 94 avalanche paths. Twenty-seven miles of the route have streams within 0.5 mile of the travel way. The route crosses 43 streams.</td>
<td>Same as Baseline Condition.</td>

</tbody>
</table>
| The SGP may cause changes in quantity of surface water and groundwater in all drainages within the analysis area. | Stream flow characteristics (daily, seasonal, annual). | Surface waters include the East Fork SFSR, Rabbit Creek, Meadow Creek, EFMC (also known as Blowout Creek), Garnet Creek, Fiddle Creek, Midnight Creek, Hennessy Creek, West End Creek, and Sugar Creek. Monthly average seasonal low flows:  
• Meadow Creek between TSF and Hangar Flats pit = 2.7 cfs  
• Meadow Creek below the diversion and above East Fork SFSR (Mine Years 7-10) = 3.8 cfs | Same as Baseline Condition. | Low flow would be reduced at some locations during some periods of the SGP operations up to 14 percent in East Fork SFSR (at USGS Gaging Station 13311250) and up to 40 percent in Meadow Creek (downstream of the Hangar Flats diversion but upstream of the confluence with East Fork SFSR). Surface flows are generally predicted to recover to pre-mine conditions within approximately 3 years after operations cease. | Same as the 2021 MMP. |
| The extent, magnitude, and duration of groundwater level changes. | Groundwater flow in the analysis area occurs primarily in the Quaternary unconsolidated deposits filling the valleys and through the unconsolidated deposits covering the mountainsides. | Same as Baseline Condition. | Dewatering of open pits lowers groundwater levels in alluvial and bedrock formations during operations and post-closure periods. These lower levels reduce flows in streams that receive groundwater discharge. There are 93 seep and spring locations within the area of groundwater drawdown that could be affected by lower water levels to the extent that any of these specific seeps or springs are receiving discharge from the aquifer affected by groundwater pumping. In most areas, groundwater levels recover within 10 years. However, groundwater levels below and directly downstream from facilities lined as part of mine closure (the TSF, TSF Buttress, Yellow Pine Pit backfill, and Hangar Flats Pit backfill) would be permanently lower due to reduced local recharge. | Same as the 2021 MMP. |
| The SGP may affect water rights. | Change in water rights availability in the SGP area. | Four existing water rights at the SGP owned by Perpetua. | Same as Baseline Condition; No changes in water rights availability. | No changes in water rights availability in the SGP area. | May affect downstream water rights. | Same as the 2021 MMP. |
| New water rights needed. | Existing water rights held by Perpetua: | 77-7285 - Groundwater right for storage and mining with diversion of 0.5 cfs for a maximum total usage of 39.2 acre-feet  
77-7141 – Groundwater right for domestic with diversion of 0.2 cfs for a maximum total usage of 11.4 acre-feet  
77-7293 – Surface water right for storage and mining for diversion of 0.25 cfs and a maximum total usage of 20 acre-feet.  
77-7122 – Surface water right for storage and mining for diversion of 0.33 cfs for a maximum total usage of 7.1 acre-feet. | Same as Baseline Condition; No new water rights required. | Up to an additional 9.6 cfs of water rights needed to support ore processing. An additional total of 0.28 cfs of groundwater rights needed for potable water supply at the Stibnite Worker Housing Facility, Burntlog Maintenance Facility, and SGLF. | Same as the 2021 MMP. |

<tr>
<td>Wetland and Riparian</td>
<td>Within the mine site focus area - Acres of wetland and riparian habitat lost due to SGP construction.</td>
<td>There are 429 acres of wetlands delineated in the mine site focus area. There are 2,665 acres of RCAs mapped in the mine site focus area.</td>
<td>Same as Baseline Condition.</td>
<td>119.8 acres of wetlands would be lost at the mine site (28% of wetlands at the mine site). 618.9 acres of riparian areas would be lost at the mine site.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td></td>
<td>Within the off-site focus area - Acres of wetland and riparian habitat lost through SGP construction.</td>
<td>There are 2,138.6 acres of wetland delineated in the off-site focus area. There are 127,389 acres of RCAs mapped in the off-site focus area.</td>
<td>Same as Baseline Condition.</td>
<td>76.3 acres of wetlands would be lost within the off-site focus area. 299.5 acres of riparian areas would be lost within the off-site focus area.</td>
<td>71.2 acres of wetlands would be lost within the off-site focus area. 352.6 acres of riparian areas would be lost within the off-site focus area.</td>
</tr>
<tr>
<td>Impacts on wetland and riparian functions¹</td>
<td>Functional units of wetlands, including high-value wetlands (i.e., Category I and II per Montana Wetland Assessment Method [MWAM]), lost due to SGP construction.</td>
<td>Existing Wetland Functions and Values of AAs assessed for the SGP are available for the analysis area.</td>
<td>Same as Baseline Condition.</td>
<td>1,054.4 functional units would be lost, including 375.9 high-value functional units.</td>
<td>1,028.3 functional units would be lost, including 370.6 high-value functional units.</td>
</tr>
<tr>
<td></td>
<td>Wetland and riparian area fragmentation.</td>
<td></td>
<td>Same as Baseline Condition.</td>
<td>39 wetlands would be crossed by new roads.</td>
<td>Six wetlands would be crossed by new roads.</td>
</tr>
<tr>
<td></td>
<td>Total area (in acres) of wetlands that would be lost.</td>
<td>See first row in this table for acreages on wetlands and RCAs</td>
<td>Same as Baseline Condition.</td>
<td>196.1 wetland acres lost.</td>
<td>191.0 wetland acres lost.</td>
</tr>
<tr>
<td>Alteration of wetland and riparian areas due to changes in water balance.</td>
<td>Wetlands within the groundwater analysis area are discussed in the Water Quantity Specialist Report (Forest Service 2022f).</td>
<td>Same as Baseline Condition.</td>
<td>4.6 acres of wetlands would be affected by drawdown. The entirety of these wetlands also would be subject to direct impacts from component construction.</td>
<td>Same as 2021 MMP.</td>
<td></td>
</tr>
<tr>
<td>Alteration of wetland and riparian areas due to changes in water quality.</td>
<td>Surface water and groundwater quality are discussed in the Water Quality Specialist Report (Forest Service 2022f).</td>
<td>Same as Baseline Condition.</td>
<td>The SGP would have the potential to impact wetland and riparian area water quality, primarily associated with sedimentation and traffic-related incidents. These impacts are discussed further in the Water Quality Specialist Report (Forest Service 2022f). These effects would be minimized through best management practices, spill prevention, and spill response measures. Effects if sedimentation and fugitive dust would be within normal range of properly maintained Forest Service roads.</td>
<td>Water quality effects on wetlands and riparian areas would be the same as the 2021 MMP, though no construction or use of Burntlog Route would eliminate water quality impacts in that area but would increase the impacts along the Johnson Creek Route that is parallel and near East Fork SFSR and Johnson Creek.</td>
<td></td>
</tr>
</tbody>
</table>

¹ Disturbance includes both temporary and permanent effects associated with transmission line construction.

<td>---------------------------------</td>
</tr>
<tr>
<td>Changes to Water Temperature WCI</td>
<td>No mining related activities.</td>
<td>Same as Baseline Condition.</td>
<td>During operations summer maximum stream water temperatures in Meadow Creek and the East Fork South Fork would decrease by up to 3.7°C due to diversion of Meadow Creek around the TNF and TSF Buttress. Upon closure and routing of Meadow Creek to the restored stream channel on top of the reclaimed TSF, summer maximum stream temperatures would increase by up to 6.8°C due to the time needed for revegetation to result in riparian shading of the stream. Over time, summer maximum stream temperatures would decline to near or below baseline conditions except for the Meadow Creek upstream of East Fork Meadow Creek which would remain 1.1°C above existing conditions.</td>
<td>Same as 2021 MMP.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Sediment and turbidity from construction of temporary roads and transmission lines</td>
<td>No mine-related traffic on existing Forest Service Roads.</td>
<td>Same as Baseline Condition.</td>
<td>Access road roads would cross 43 streams and transmission lines would cross 37 streams. Construction: 6.5 miles (18% of routes) would be within 100 feet of streams. Operations: 1.56 miles (4% of routes) would be within 100 feet of streams. Sedimentation and fugitive dust predicted to be within normal range of properly maintained Forest Service roads.</td>
<td>Same as 2021 MMP except 6.5 miles of streams would be within 100 feet of streams during operations.</td>
<td>Same as Baseline Condition.</td>
</tr>
<tr>
<td>Change in Access to fish habitat through culverts from road construction</td>
<td>Use of existing roads and culverts.</td>
<td>Same as Baseline Condition.</td>
<td>Culvert replacements on the Burntlog Route may increase or re-establish habitat access for native and non-native species.</td>
<td>Same as Baseline Condition.</td>
<td></td>
</tr>
<tr>
<td>Change in amount of stream habitat by barrier removal and new barriers</td>
<td>Existing barriers in place.</td>
<td>Same as Baseline Condition.</td>
<td>Removal of the box culvert in the EFFSFR would provide additional access to around 6 km of intrinsic potential habitat for Chinook salmon and steelhead, with the removal of the barrier at the YPP lake cascade adding more than an additional 2.5 km for Chinook salmon. Removal of these barriers will improve access to nearly 33 km of habitat for bull trout and westslope cutthroat trout, thus improving genetic integration. Removal of barriers in the downstream end of Fiddle Creek would provide an additional 2 km of habitat for bull trout and westslope cutthroat trout. Creation of a partial gradient barrier in East Fork Meadow Creek would provide additional access to habitat for bull trout and westslope cutthroat trout. The removal and addition of barriers in Meadow Creek would ultimately result in a reduction in access to the Meadow Creek headwaters.</td>
<td>Same as 2021 MMP.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Changes to Chemical Contaminants Associated with Spills</td>
<td>No mining related activities.</td>
<td>Same as Baseline Condition.</td>
<td>Effects of spills would be managed via application of Forest Service requirements and project design features to minimize effects.</td>
<td>Same as 2021 MMP. Effects from spills would be potentially more significant because 6.5 miles of the permanent access road would be within 100 feet of streams during operations.</td>
<td></td>

<th>No Action Alternative</th>
<th>2021 MMP</th>
<th>Johnson Creek Route Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acres of disturbance and the proximity of the proposed mine operations to high-value habitats such as crucial and or high-value big game ranges, wetlands, and seep and spring areas.</td>
<td>N/A</td>
<td>Same as Baseline Condition.</td>
<td>Direct Habitat Impacts: 3,266 acres</td>
<td>Same as the 2021 MMP, with the exception of the Burntlog Route.</td>
</tr>
<tr>
<td>Change in noise levels (in decibels) in—or in proximity to—wildlife habitat</td>
<td>Existing ambient sound levels were measured at various noise-sensitive receptor sites and varied between 34 and 64 dBA.</td>
<td>Same as Baseline Condition.</td>
<td>Ongoing noise levels would attenuate to 55 dBA within 0.8 miles of the disturbances based on distance alone. Temporary disturbances (e.g., blasting, winter road maintenance) would be audible further away. Construction: Mine site noise would attenuate to 55 dBA at 0.8 mile from source; access road construction would attenuate to 55 dBA at 0.57 mile on distance alone. Operations: Based on distance alone, mine site noise would attenuate to 55 dBA at 1.5 miles; blasting would attenuate to 55 dBA at 2.2 miles; road maintenance would attenuate at 0.4 to 0.55 miles; and mine traffic would be below the threshold at 49 dBA. Closure: Noise impacts would be similar to the construction phase.</td>
<td>Same as the 2021 MMP, with the exception of the Burntlog Route — noise from traffic on Johnson Creek Route would be similar. Helicopter installation of utility structures would reduce habitat impacts but would introduce noise that could affect sensitive species. Construction: Helicopter use would attenuate to 55 dBA approximately 1.7 miles from the source of the activity on distance alone.</td>
</tr>
<tr>
<td>The SGP may affect wildlife by introducing barriers to movement, including the mine site, infrastructure, new/existing maintained roads, new transmission line.</td>
<td>Miles of new roads proposed for the SGP.</td>
<td>Access Roads – existing roads – 89 miles Utilities – existing roads – 30 miles</td>
<td>Access Roads – 15 miles new road on Burntlog Route Cabin Creek OSV route – 10.4 miles groomed OSV route Utilities – new utility access roads – 25 miles</td>
<td>Access Roads – No new access road miles. No Cabin Creek OSV route.</td>
</tr>
<tr>
<td>Acres of disturbance for new and upgraded transmission lines.</td>

<td>The SGP may affect public safety on the roads used by mine vehicles during construction, operation, closure, and reclamation activities.</td>
<td>Number of SGP-related vehicles and trips on public roads.</td>
<td>SGP area is dominated by unpaved roads, one state highway, and county roads. The road segment of highest safety and traffic concern is Warm Lake Road.</td>
<td>Same as Baseline Condition.</td>
<td>Major The increased mine-related traffic on Warm Lake Road and other access roads increases the potential for accidents.</td>
<td>Major The use of Johnson Creek Route during operations, closure, and reclamation would increase safety issues by routing heavy truck traffic through the Village of Yellow Pine and the general public traveling on the same road as large mining equipment.</td>
</tr>
<tr>
<td>The SGP may affect human health or exposure to hazards.</td>
<td>Current public health statistics and descriptors.</td>
<td>Valley County ranks sixth best in state for health outcomes and fourth best in the state for overall health factors</td>
<td>Same as Baseline Condition.</td>
<td>The economic benefits could lead to continued or improved access to health services, better nutrition, and better overall well-being for the local community. Potential negative economic impacts associated with “boom and bust” could result in negative health impacts during closure and beyond.</td>
<td>Same as the 2021 MMP.</td>
</tr>
<tr>
<td>Changes in health metrics such as soil, air, and water quality along with resulting metal concentrations in site biota</td>
<td>Baseline air quality measurements indicate current concentrations of the criteria air pollutants are well below the NAAQS. Soil - legacy mine tailings are known to contain elevated levels of arsenic and antimony. Surface Water – The chemicals of concern for public health were arsenic, antimony, and mercury. Each of the inventoried waterbodies (except for West End Creek) are CWA Section 303(d) listed. The causes for listing of these waters are associated with arsenic, with the East Fork SF SR also being listed for antimony (downstream of Meadow Creek) and</td>
<td>Same as Baseline Condition.</td>
<td>Air - Negligible: predicted ambient air concentrations at boundary where public is allowed shown to be below NAAQS. Soil - Minor: exposures by recreationists to impacted soil materials would be of relatively low frequency, short duration, and low magnitude during construction and operations of the SGP; closure and reclamation activities assumed to lead to overall reduction in chemical impacts to surface soil. Potential negative impacts would be off-set by positive impacts from reclamation of legacy contamination. There would be a concomitant reduction in these pollutants in biota harvested from the site area. Surface Water - Negligible. Exposures are expected to be of limited magnitude and short duration. Water treatment systems and design features lead to comparable or lower</td>
<td>Same as the 2021 MMP.</td>
<td></td>

<td>--------------------------------</td>
</tr>
<tr>
<td></td>
<td>Sugar Creek also being listed for mercury.</td>
<td>Increased risk of natural hazards (wildfire, avalanche, landslide).</td>
<td>The entire SGP area presents potential flash-flood and debris-flow hazards that also can cause severe injury or death, or block access. Some portions of the mine site also are conducive to landslides and avalanches. Fires can cause severe injury or death for travelers, recreationists, and Forest Service and Perpetua employees, as well as damage to property.</td>
<td>Moderate</td>
<td>Moderate None of the positive impacts associated with improvement and development of the Burntlog Route. Johnson Creek Route has steeper topography and terrain and there are more areas of landslides and rockfalls along the Johnson Creek Route than there are along the Burntlog Route. Safety issues also are increased by heavy truck traffic through the Village of Yellow Pine and the general public traveling on the same road as large mining equipment.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>The SGP may affect infrastructure and services as related to emergency services, medical services, law enforcement, social services, sanitation, and wastewater treatment.</td>
<td>Capacity of existing infrastructure and services to meet anticipated increased use.</td>
<td>Due to the remote nature, most of the SGP area is located more than 30 miles from the nearest local emergency services.</td>
<td>Same as Baseline Condition.</td>
<td>Moderate and positive Emergency medical technicians and emergency equipment and supplies would be on-site, including an ambulance, first aid, and medical supplies.</td>
<td>Same as the 2021 MMP.</td>
</tr>
<tr>
<td>The SGP may cause public health effects related to changing environmental conditions.</td>
<td>Disruption of recreational areas during construction, operation, and closure and reclamation.</td>
<td>Recreation is a major use throughout much of the SGP area; activities commonly include hunting, fishing, sightseeing, hiking, camping, all-terrain vehicle use, snowmobiling, and horseback riding.</td>
<td>Same as Baseline Condition.</td>
<td>Negligible Displacement of project-area recreational activities would be offset by improved access to alternative recreational areas.</td>
<td>Same as the 2021 MMP.</td>
</tr>
<tr>
<td>The SGP may cause changes to recreation setting, access, facilities, and/or opportunities.</td>
<td>Psychological effects due to noise.</td>
<td>Sound levels at the 12 baseline noise measurement locations in the SGP area ranged from 34 dBA to 64 dBA.</td>
<td>Same as Baseline Condition.</td>
<td>Negligible Predicted noise levels would be under, at, or slightly over the outdoor threshold level of 55 dBA.</td>
<td>Same as the 2021 MMP.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Recreation</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Access to the areas/facilities accessed from Thunder Mountain Road (FR 30375) east of the SGP would be modified due to closure of Stibnite Road (CR 50-412) and creation of the Burntlog Route, which would provide motorized access (year-round) to areas that currently do not have motorized access. Winter access would be increased along Cabin Creek Road due to new OSV route. There would be direct access to Thunder Mountain Road through the SGP during operations, in addition to access via the Burntlog Route. The re-routed segment of the Burntlog Route would provide increased motorized access to areas without such access currently. Access to several OSV routes would be affected by plowing of Johnson Creek Road, Warm Lake Road, and the Burntlog Route. Construction activities for transmission lines and the maintenance facility may result in delays or detoured access.</td>
<td>Changes in motorized access (including restrictions and/or changes in maintenance) to recreation opportunities.</td>
<td>State and County roads provide access to connecting unpaved Forest Service roads, which provide access to NFS lands and facilities.</td>
<td>Current access to the area via Johnson Creek Road and Stibnite Road would remain unimpeded. In general, areas that are inaccessible to motorized vehicles would continue to be inaccessible to vehicles or certain vehicle types in summer.</td>
<td>Similar to the 2021 MMP, except there would be no Burntlog Route and resulting new motorized access to areas from these facilities. Access to several OSV routes would be affected by plowing of Johnson Creek Road and Warm Lake Road.</td>
<td></td>

</table>
| Changes in recreation physical setting characteristics | Designated ROS classes in the analysis area vary by season, and include Rural, Roaded Natural, Roaded Modified, Semi-Primitive Motorized, Semi-Primitive Non-Motorized, and Primitive. Estimated existing ROS physical settings are similar. | Generally, existing designated ROS classes and physical recreation setting characteristics would remain as is. Modifications to the recreation setting in the SGP area continued low level of unauthorized motorized use, and increased winter motorized access and use could lead to changes in the designated ROS class and/or ROS physical setting of some areas due to additional motorized use both in the summer and winter. | Acreage of Estimated ROS Physical Setting Classes – Summer/Winter:  
  - Primitive: 17,278/21,370 acres  
  - Semi Primitive Non-Motorized: 218,512/245,210 acres  
  - Semi-Primitive Motorized: 83,497/240,387 acres  
  - Semi-Primitive Motorized Groomed (winter only): 50,436 acres (this acreage overlaps other features)  
  - Roaded Natural: 140,594/7,511 acres  
  - Rural: 81,450/26,853 acres | Acreage of Disturbance to ROS Physical Setting Classes During Operations – Summer/Winter:  
  - Primitive: 0 acres  
  - Semi Primitive Non-Motorized: 0 acres  
  - Semi-Primitive Motorized: 42/364 acres  
  - Semi-Primitive Motorized Groomed (winter only): 163 acres  
  - Roaded Natural: 685/387 acres  
  - Rural: 345/322 acres | Similar to the 2021 MMP, except there would be no inconsistencies with existing designated ROS classes related to the Burntlog Route or plowing of the Burntlog Route. Inconsistency with the existing designated ROS class for Johnson Creek and Stibnite Roads in the winter would not be temporary during construction (as in the 2021 MMP) but would continue through operations and reclamation because the roads would be plowed as part of the Johnson Creek Route. Acreage of Estimated ROS Physical Setting Classes During Operations – Summer/Winter:  
  - Primitive: 0/0 acres  
  - Semi Primitive Non-Motorized: 0/0 acres  
  - Semi-Primitive Motorized: 43/212 acres  
  - Semi-Primitive Motorized Groomed (winter only): 113 acres  
  - Roaded Natural: 387/34/3 acres  
  - Rural: 353/53/6 acres |
| Changes in recreation facilities (trails, campgrounds, trailheads) | The Warm Lake area contains most of the developed recreation facilities (apart from trailheads). Scattered campgrounds and other facilities also are located in the Big Creek and Landmark areas and along Johnson Creek Road around and south of Yellow Pine. Developed recreation facilities primarily include campgrounds, cabins/lookouts, trailheads, and trails. | Same as Baseline Condition | The Stibnite Mining District Interpretive Site would be closed until after mine reclamation. Mine components would alter the setting of recreation facilities adjacent to them to a more developed setting due to increased man-made development, noise, traffic, etc. These components include the mine and facilities at the SGP, Burntlog Route, upgraded transmission lines, new transmission line to the SGP, Johnson Creek substation, cell tower on Meadow Creek Lookout Road, use of Warm Lake Road, and temporary use of the Johnson Creek Route. | Similar to the 2021 MMP. The Burntlog Route would not be built; therefore, there would be no resulting displacement or increase in recreation use from this route. |
| Changes in recreation use, potentially due to changes in recreation facilities, opportunities, access, and setting. | Developed recreation use is limited to the developed recreation facilities (i.e., overnight facilities) located primarily in the Warm Lake, Landmark and Johnson Creek Road areas. Most recreation in the analysis area is dispersed use, which occurs outside of developed recreation sites. | Existing recreation use would continue. Some unauthorized motorized use may continue to occur off of existing roads and motorized trails. Motorized winter use has expanded in recent years, and may continue to expand in the future, resulting in additional OSV routes and additional areas receiving winter motorized use. | There would be public access through the SGP, which may result in less displacement of use to areas/facilities accessed from Thunder Mountain Road (FR 50375). In addition, there would be less likelihood for increased dispersed recreation use along the Burntlog Route as this route would only be available for public use when the route through the SGP was closed. Some recreation use may return to the SGP area after reclamation; however, due to the changes in the recreation setting, some use may be displaced to areas where the recreation setting is more natural. | Similar to the 2021 MMP. The Burntlog Route would not be built; therefore, there would be no resulting displacement or increase in recreation use from this route. |

<tr>
<td>Changes in tourism and recreational based businesses.</td>
<td>No increase in tourism sector from current conditions and trends.</td>
<td>Same as Baseline Condition; including no improvement of the lingering effects of historic mining on the environment.</td>
<td>Limited displaced recreation due to low use levels and likely local area relocation. Negligible adverse impact to local area tourism economy expected. Potential for adverse impacts to specific individual recreation businesses and/or communities.</td>
<td>Long-term traffic growth in proximity to campgrounds, dispersed camping areas, trailheads, and recreational residences would increase activity and noise which could change the recreational setting and reduce visitor recreation experience.</td>
<td></td>
</tr>
<tr>
<td>Changes in transportation and infrastructure.</td>
<td>No major changes expected that would result in economic activity or development changes that would substantially impact the local area’s current economic conditions.</td>
<td>Same as Baseline Condition.</td>
<td>Local area infrastructure and/or roadway use changes would not result in any major changes in economic activity or development that would result in substantial impacts on the local area’s economy.</td>
<td>The village of Yellow Pine would experience an increase in future traffic (estimated to average 60 vehicles daily) from SGP vehicle use of the Johnson Creek Route to the mine site during SGP operations.</td>
<td></td>
</tr>
<tr>
<td>SGP mineral extraction revenue.</td>
<td>Market values of extracted minerals.</td>
<td>No mineral extraction.</td>
<td>Same as Baseline Condition.</td>
<td>SGP mineral production projected value (after refining) is approximately $7 billion over the SGP operating life.</td>
<td>Similar to 2021 MMP.</td>
</tr>
<tr>
<td>Incremental costs to the SGP as a result of proposed facility and operation modifications.</td>
<td>Changes in the SGP’s construction costs and/or future operating expenses.</td>
<td>The SGP is not built, and no mine operations occur.</td>
<td>No costs for SGP construction or future operations and maintenance (O&amp;M) expenses.</td>
<td>Total initial construction of SGP estimated to cost approximately $1.1 billion. Total annual operations estimated to cost approximately $270 million/year.</td>
<td>Marginal increase in construction costs compared to 2021 MMP from upgrade of Johnson Creek Route instead of Burntlog Route construction. SGP total construction, O&amp;M, and financial costs from use of Johnson Creek Route would increase by up to $174 million. Marginal net increase in future annual O&amp;M cost due to longer haul distances.</td>
</tr>
<tr>
<td>Values and benefits associated with ecosystem conditions including water quality and aquatic habitat. (The reader is also referred to summaries for other resource areas in this table.)</td>
<td>Removal of legacy mine tailings and waste rock. Volume and disposition of mineralized wastes from operations Fish habitat and fish population conditions.</td>
<td>Legacy mine waste in Meadow Creek valley from historical mining. SGP area streams currently provide habitat for fish species, however, barriers associated with historical mining affect volitional fish access to portions of that habitat.</td>
<td>Same as Baseline Condition.</td>
<td>Removal of legacy mine waste, management of project mineralized wastes, and active water treatment result in water quality conditions in the mine area with lower dissolved antimony and arsenic concentrations compared to baseline. These activities utilize O&amp;M expenditures during operations that continue into the post-closure period. Long term impacts to fish habitat and fish populations associated with project construction, operations, and closure. Restored fish passage to habitat available upstream of the existing Yellow Pine pit.</td>
<td>Similar to 2021 MMP.</td>
</tr>
<tr>
<td>Impacts to an IRA from SGP construction and operations</td>
<td>Roadless characteristics</td>
<td>There is an existing IRA in the vicinity of the proposed Burntlog Route</td>
<td>Same as Baseline Condition.</td>
<td>Development and use of the Burntlog Route would affect roadless characteristics in three IRAs.</td>
<td>The use of the Johnson Creek Route would not incur any impacts to roadless area characteristics that would be associated with the construction of the Burntlog Route.</td>
</tr>

<tr>
<td>Location of SGP facilities, including roads and transmission lines in relation to minority or low-income residents.</td>
<td>There are no environmental justice communities in the SGP area.</td>
<td>Same as Baseline Condition.</td>
<td>There would be no direct effect of SGP facilities on environmental justice communities.</td>
<td>None of the SGP facilities would be on reservation lands; therefore, there would be no direct effect of SGP facilities on Tribal environmental justice communities.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Differences in access to public lands.</td>
<td>Public and Tribal member access is available throughout the SGP area except in areas previously used for mining. There are no minority and low-income populations in the SGP area that would be affected by differences in public and Tribal member access. Tribal members use public lands within the PNF and BNF to access cultural and subsistence resource areas.</td>
<td>Same as Baseline Condition.</td>
<td>Construction and operations could impact access to traditional use areas and subsistence resources through habitat loss; behavioral disturbance to resources from increased noise and human activity; and concerns about contamination of resources. Burntlog Route and new OSV groomed trails would provide new and/or improved access to the SGP area and vicinity, which could have a positive impact by providing motorized access to cultural sites and subsistence resources. Public and Tribal member access also would be provided through the mine site by constructing new road to link Stibnite Road to Thunder Mountain Road. Access and use increases could result in potential indirect adverse impacts to Tribal members due to increased human activity.</td>
<td>Same as 2021 MMP, except for: No new and/or improved access from construction or use of the Burntlog Route. Upgrades to Johnson Creek Route and use of Warm Lake, Johnson Creek, and Stibnite roads as the primary access route to the mine site would result in greater impacts to Tribal environmental justice communities.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Change in traditional Tribal practices and/or access to Tribal resources.</td>
<td>Tribal access and use of the region have long-standing and on-going current cultural importance and subsistence value for many Tribal members.</td>
<td>Same as Baseline Condition.</td>
<td>Restricted access to traditional use areas would occur in the 14,221 acres of public lands within the Operations Area Boundary. Additional use of the area caused by road improvements could impact Tribal members by potentially increasing unauthorized motorized use, causing distractions, and changing natural conditions of traditional Tribal practices.</td>
<td>Same as 2021 MMP.</td>
<td>Same as 2021 MMP.</td>
</tr>
<tr>
<td>Change in traditional Tribal practices and/or access to sacred sites.</td>
<td>Based on ethnographic information received from the Nez Perce Tribe, Shoshone-Bannock Tribes, and Shoshone-Paiute Tribes, sacred sites do exist in the analysis area, although exact locations are not public information.</td>
<td>There would be no potential impact to sites of cultural significance.</td>
<td>Specific information from the Tribes regarding the exact nature, duration, and location of impacts on sacred sites is confidential. Based on the information provided to the Forest Service by the Tribes, it is expected that the SGP-related impacts would be of a type and/or magnitude to represent an adverse environmental justice impact to the Tribal environmental justice communities.</td>

<tr>
<td></td>
<td></td>
<td>near-alpine habitat in the highest elevation areas. Wildfires have continually altered the wilderness landscape, creating brush fields, large lodgepole pine stands, extensive snag patches, and variations in species and age classes of vegetation.</td>
<td>Route in the headwaters of Riordan Creek would increase the risk of non-native plant species spreading into the FCRNRW. The use of the Johnson Creek Route during construction and construction of the Burntlog Route could disturb wildlife and change the distribution of big game within the FCRNRW. During the 3 years of construction, the increase in human activity near the western FCRNRW boundary could change ecological processes in areas where non-native plant species establish. During the 15 years of operation, mine traffic and recreation use on the Burntlog Route could increase the potential for non-native plant species to spread into the FCRNRW. Where established, non-native plants could alter ecological processes. The 50 vehicles per day, the Burntlog Route road maintenance, and recreation use of access roads adjacent to the FCRNRW would create additional opportunities for solitude within the FCRNRW.</td>
<td>mine operation would reduce the miles of road near the FCRNRW and reduce the potential for non-native plant species to spread into the FCRNRW. Mine vehicles and recreation use would be on existing roads. The use of existing roads for mine traffic would reduce the area adjacent to the FCRNRW where vehicle traffic could disturb big game species. Surface disturbance from mineral exploration, reseeding disturbed areas, and monitoring activities would be 3 miles from the FCRNRW boundary. The natural quality of wilderness character would be the same as existing conditions.</td>
<td></td>
</tr>
<tr>
<td>The SGP could change the quality of wilderness character in designated or recommended wilderness areas.</td>
<td>Distance of designated or recommended wilderness from sights and sounds of human activity from SGP activities.</td>
<td>The FCRNRW and recommended wilderness areas contain diverse vegetation and wildlife species. Vegetation varies from ponderosa pine/bluebunch wheatgrass or Idaho fescue, and Douglas- fir/ninebark or alpine meadow/Idaho fescue. Large lodgepole pine stands, extensive snag patches, and variations in species and age classes of vegetation.</td>
<td>Sights and sounds of human activity from mineral exploration and monitoring activities would be 3 miles from the FCRNRW boundary.</td>
<td>Noise from the construction of the Burntlog Route would be audible along the boundary of the FCRNRW. Decreasing the distance between the Burntlog Route and the FCRNRW boundary would increase the area where noise from construction activities would be audible. Noise from road maintenance activities and recontouring slopes during closure on the Burntlog Route could be heard along the boundary of the FCRNRW depending upon topography and weather conditions and would reduce opportunities for solitude within the FCRNRW.</td>
<td>Using the Johnson Creek Route during construction, operation, and closure and reclamation would eliminate impacts on the FCRNRW associated with the Burntlog Route.</td>
</tr>
<tr>
<td>Reduced opportunities for self-reliant recreation within designated or recommended wilderness.</td>
<td>The FCRNRW and recommended wilderness areas provide opportunities for solitude and primitive recreation.</td>
<td>Opportunities for solitude would be the same as existing conditions.</td>
<td>The decreased distance between the Burntlog Route and the FCRNRW boundary would increase the area where noise from SGP activities is audible. The extent where noise is audible would reduce opportunities for solitude within the FCRNRW. If wilderness visitors avoid the FCRNRW areas accessed through the SGP or adjacent to the Burntlog Route, increased recreation in recommended wilderness areas could reduce opportunities for solitude within the FCRNRW.</td>
<td>Using the Johnson Creek Route during construction, operation, and closure and reclamation would eliminate impacts on the FCRNRW associated with the Burntlog Route. Using Johnson Creek Route during the 15 years of mine operation could increase wilderness visits to recommended wilderness areas or other areas of the FCRNRW.</td>

<td>A reduction of approximately 200 acres of SGP facilities within four IRAs (Meadow Creek, Horse Heaven, Caton Lake, and Reeves Creek) would occur. After mine closure, the TSF and TSF Buttress would remain in the Meadow Creek and Horse Heaven IRAs.</td>
</tr>
</tbody>
</table>
The SGP could impact research values or ecosystem conditions within RNAs. Change in vegetation community composition and structure within an RNA. Change in number of vehicles using roads and human activity within or immediately adjacent to an RNA. Changes to water quality (chemistry, temperature) or quantity within an RNA.

The six RNAs within the analysis area provide opportunities to conduct research and provide a control site to evaluate ecological conditions and processes within the Intermountain West. Surface exploration and seeding of disturbed areas at the SGP would be over 5 miles from the six RNAs. The research values and ecological site conditions within the RNAs would be the same as existing conditions.

Areas where non-native plant species become established would reduce the Chilcoot Peak RNA values in the long term. Changes to the vegetation community composition would result in a loss of research values and ecological conditions within an RNA. Dust deposited on vegetation could change vegetation conditions and ecological processes within the Chilcoot Peak RNA. Human caused fire ignitions that spread into the Chilcoot Peak RNA could change the existing fire regime and reduce the RNA’s research values related to ecological process. Indirectly, if forest visitors avoid areas near the Burntlog Route or the SGP there could be an increase in recreation use on trails and roads adjacent to an RNA. Culverts along a segment of FR 447 of the Burntlog Route could change the movement of sediment, woody debris, and other organic material. Additional culverts installed along the Burntlog Route could indirectly change local hydrologic conditions within the Chilcoot Peak RNA and alter ecological processes long term. Changes in ecological processes would reduce the Chilcoot Peak RNA values.

The use of the Johnson Creek Route for mine access could increase recreation use along the South Fork Salmon River and Big Creek drainages from forest visitors avoiding the SGP. Increased recreation use on trails could increase the potential for non-native invasive plant species into RNAs. The potential loss of RNA values could be less than the 2021 MMP as the roads and trails open to public use are several miles from the closest RNA. The Johnson Creek Route Alternative would occur farther away from the Chilcoot Peak RNA. Potential impacts to the Chilcoot Peak RNA would be fewer and of lesser intensity under this alternative.

Tribal Rights and Interest

The SGP would impact tribal resources, restrict tribal access, and reduce viability and/or availability of culturally significant fish, wildlife, and plants. Presence of TCPs, CLs, sacred sites or places, and resource harvesting and gathering areas impacted by an increase in ground disturbance.

Tribal resource harvesting and gathering areas and traditional use sites are in the analysis area, including the Old Thunder Mountain Road (FR 440) travel route, portions of the historic Burnt Log Road travel route, the Johnson Creek Road travel route, the East Fork SFSR watershed system associated with a potentially eligible TCP District historic property, and the Riordan Lake shore. Ground disturbance is currently from approved activities confined to a small area of private and NFS lands and use of existing roads and facilities.

Ground disturbance would increase over baseline and would physically impact the East Fork SFSR watershed system, plus an undisclosed number of other tribal resources, such as tribal travel routes along the Burntlog Route.

The use of the Johnson Creek Route Alternative for mine access could increase recreation use along the South Fork Salmon River and Big Creek drainages from forest visitors avoiding the SGP. Increased recreation use on trails could increase the potential for non-native invasive plant species into RNAs. The potential loss of RNA values could be less than the 2021 MMP as the roads and trails open to public use are several miles from the closest RNA. The Johnson Creek Route Alternative would occur farther away from the Chilcoot Peak RNA. Potential impacts to the Chilcoot Peak RNA would be fewer and of lesser intensity under this alternative.
<table>

<tr>
<th>Issue</th>
<th>Indicator</th>
<th>Baseline Conditions</th>
<th>No Action Alternative</th>
<th>2021 MMP</th>
<th>Johnson Creek Route Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Presence of TCPs, CLs, sacred sites or places, and resource harvesting and gathering areas impacted by an increase in audible elements (noise and vibrations).</td>
<td>Tribal resource harvesting or gathering areas and traditional use sites are in the analysis area, including the Old Thunder Mountain Road (FR 440) travel route, Burnt Log Road travel route, the Johnson Creek Road travel route, the East Fork SFSR watershed system associated with a potentially eligible TCP District historic property, and the Riordan Lake shore. Currently the only noise and vibrations disturbance is from approved activities, including underground exploration on private land, with occasional blasting (short-term high noise levels and ground vibrations).</td>
<td>Same as baseline conditions.</td>
<td>Noise and vibrations would increase and include blasting, drilling, and ore crushing at the mine site; temporary increases during construction; and increases due to use of roads during construction and operations (Forest Service 2022h). The increase in noise and vibrations would likely be perceived by tribal members as a reduction in the integrity of setting and solitude and may discourage or detract from potential TCPs, CLs, sacred sites or places, and tribal use of traditional areas.</td>
<td>Same as 2021 MMP except: Upgrades to Johnson Creek Route and use of Johnson Creek and Stibnite roads as the primary route to the mine site for the life of the SGP would result in greater impacts to tribal resources, including the Johnson Creek Road travel route, along these roads due to increased noise and traffic. The Burninglog Route would not be constructed, therefore there would be no noise and vibrations related to construction, use, and maintenance of that route.</td>
<td></td>
</tr>
<tr>
<td>Presence of TCPs, CLs, sacred sites or places, and resource harvesting and gathering areas impacted by the visual range of new tall or massive SGP components.</td>
<td>Tribal resource collection areas and traditional use sites are in the analysis area, including the Old Thunder Mountain Road (FR 440), the East Fork SFSR system, and the Riordan Lake shore. The Yellow Pine pit and tailings piles from historical mining activities are present along with a large, capped heap leach pile from mining in the 1980s. The transmission line already exists between Cascade and the village of Yellow Pine.</td>
<td>Same as baseline conditions.</td>
<td>The 2021 MMP would include increased visual components through new open pits, a TSF, and TSF Butteress; new access routes; and a segment of new transmission line. The viewsheds of portions of the East Fork SFSR watershed system, Riordan Lake, and the Old Thunder Mountain Road travel route, would be altered (Forest Service 2022i). The increase in visual impacts likely would be perceived by tribal members as a reduction in the integrity of setting and solitude and may discourage or detract from potential TCPs, CLs, sacred sites or places, and tribal use of traditional areas.</td>
<td>Same as 2021 MMP, except: Johnson Creek Route Alternative would not include the Burninglog Route, which would reduce visual effects at Riordan Lake and other traditional use areas along that route. Addition of potential impacts to the Johnson Creek Road travel route.</td>
<td></td>
</tr>
<tr>
<td>Changes in tribal access due to the restricted access to Operations Area Boundary.</td>
<td>Tribal access and use of the region has had long-standing and on-going cultural importance and subsistence value. Currently there is no restricted access on NFS lands in the SGP area. Some restrictions are in place on private lands.</td>
<td>Same as baseline conditions.</td>
<td>The SGP would restrict tribal access to 14,221 acres within theOperations Area Boundary, potentially restricting access to usual and accustomed fishing places, streams and fountains, and potential TCPs, CLs, sacred sites or places within that area. However, public and tribal access would be provided through the mine site (Forest Service 2022h). Impact would be localized, long term, and moderate to major. Burninglog Route and new over-snow vehicle groomed trails would provide new and/or improved access to the SGP mine area and vicinity, including the Riordan Lake area and FCNWR, which could have a negative impact to tribal members if there is an actual or perceived decrease in their access to, availability, and/or quality of tribal resources or a positive impact by providing Tribes year-round access to previously inaccessible traditional use areas. Length of time of restricted access is 20 years. This could result in loss of tribal cultural practices important to tribal identity.</td>
<td>Same as 2021 MMP, except: Burninglog Route would not be constructed. Addition of potential impacts to the Johnson Creek Road travel route Stibnite Road would not be returned to its pre-mining width and traffic would be greatly reduced. This could encourage use of tribal resources east of the mine.</td>
<td></td>
</tr>

<td>-------------------------------</td>
</tr>
<tr>
<td>Changes to water quality and quantity of both surface water and groundwater in relation to how it affects wildlife, fisheries, vegetation, or other resources.</td>
<td>The East Fork SFSR watershed supports wildlife, wildlife habitat, and fisheries. The 1863 Treaty with the Nez Perce Tribe reserved the use of springs and fountains including perpetual rights-of-way to and from them.</td>
<td>Same as baseline conditions.</td>
<td>Long-term reduction in flows of streams, springs, and seeps receiving groundwater recharge. Water quality of surface flow departing from the Operations Area Boundary would be the same or better than baseline conditions (Forest Service 2022c). Surface water available for tribal use in the area would not be impacted above human drinking water standards by the SGP.</td>
<td>Same as 2021 MMP.</td>
<td></td>
</tr>
<tr>
<td>Changes to species viability and/or availability for tribal harvest of fish.</td>
<td>Tribes fish, hunt, and gather plants in the SGP area. Currently the Yellow Pine pit passage barrier blocks fish passage, and there are legacy chemical contaminants in downstream waters from historic mining. The SFSR and tributaries are an aquatic stronghold and recovery area for fish species of cultural significance. Tribes are managing fish and restoring habitat within this area.</td>
<td>Same as baseline conditions.</td>
<td>The SGP would affect fish and fish habitat through stream channel changes, increased stream temperature, loss of habitat, and behavioral changes (Forest Service 2022c). This could impact a Tribe’s ability to harvest fish in their usual and accustomed fishing places. Population-level effects are not expected from construction, but after reclamation the net effect would be: A loss of habitat quality and quantity for Chinook salmon, bull trout, and cutthroat trout. A net gain of habitat quality and quantity for steelhead trout. Water quality improvements from removal of legacy mine materials would partially, but not completely, offset geochemical impacts associated with the SGP (Forest Service 2022c). Use of Johnson Creek Route during construction, may impede tribal fisheries restoration activities along Johnson Creek road.</td>
<td>Same as 2021 MMP, except: A loss of habitat quality and quantity of habitat for steelhead trout. Use of Johnson Creek Route for the life of the mine (approximately 20 years), may impede tribal fisheries restoration activities along Johnson Creek road.</td>
<td></td>
</tr>
<tr>
<td>Changes to species viability and/or availability for tribal harvest of wildlife.</td>
<td>Tribes fish, hunt, and gather plants in the SGP area.</td>
<td>Same as baseline conditions.</td>
<td>The SGP would affect wildlife, including special-status species and species of cultural importance, through loss of habitat (Forest Service 2022g). Loss of habitat may in turn impact a Tribe’s ability to harvest and manage their traditional wildlife resources in the SGP area. Ground disturbance/Direct habitat impacts: 3,266 acres.</td>
<td>Same as 2021 MMP, except: Ground disturbance/Direct habitat impacts: 3,095 acres. Burntlog Route would not be constructed, therefore no habitat fragmentation or wildlife displacement in this area.</td>
<td></td>
</tr>
<tr>
<td>Changes to species viability and/or availability for tribal harvest of plants.</td>
<td>Tribes fish, hunt, and gather plants in the SGP area.</td>
<td>Same as baseline conditions.</td>
<td>The SGP would affect plant species of cultural importance through varying degrees of impacts to vegetation and special status plants that would contribute to an adverse cumulative impact on these resources (Forest Service 2022f). Loss of habitat may in turn impact a Tribe’s ability to harvest and manage their traditional plant resources in the SGP area. Revegetation in these areas would contribute to cumulative benefits, including ability of Tribes to harvest and manage their traditional plant resources in the SGP area. Acres of vegetation disturbance/clearing: 3,562 acres.</td>
<td>Same as 2021 MMP, except: Acres of vegetation disturbance/clearing: 3,269 acres.</td>
<td></td>
</tr>
<tr>
<td>Acres of access and traditional use areas that would be unavailable for the duration of mining activities to exercise treaty rights.</td>
<td>Tribes access their usual and accustomed fishing places, hunting areas, and plant gathering areas consistent with their reserved rights.</td>
<td>Same as baseline conditions.</td>
<td>The long-term loss of approximately 13,441 acres of federal land within the Operations Area Boundary: A localized, long-term, and moderate to major impact for access to specific use areas. Public and tribal access would be provided through the mine site (Forest Service 2022b).</td>
<td>Same as 2021 MMP.</td>

</table>
3.0 AFFECTED ENVIRONMENT

3.1 Introduction

Chapter 3 describes the existing natural and human environment that would potentially be affected by the SGP. The natural and human environment is further divided into resources or resource uses - physical environment, biological resources, and social resources/environment. Each resource section is organized as follows: a brief introduction and scope of analysis including a definition of the analysis area specific to the resource; relevant laws, regulations and policies; and existing conditions of the resource in the analysis area.

This SDEIS is purposely designed to efficiently detail what is necessary in order to understand the affected environment and environmental effects related to the alternatives that are evaluated. Many of the subsections of this SDEIS summarize more detailed information that is discussed in specialist reports which are cited in the subsections. These reports include any information that has become available since the DEIS was released in August 2020. Readers who are interested in reviewing the more detailed information may download the specialist reports of interest from the same website hosting this SDEIS. The specialist reports that are available include:

- Air Quality Specialist Report (Forest Service 2022a)
- Climate Change Specialist Report (Forest Service 2022b)
- Soils and Reclamation Cover Materials Specialist Report (Forest Service 2022c)
- Noise Specialist Report (Forest Service 2022d)
- Surface Water and Groundwater Quantity Specialist Report (Forest Service 2022e)
- Surface Water and Groundwater Quality Specialist Report (Forest Service 2022f)
- Vegetation: General Vegetation Communities, Botanical Resources, and Non-Native Plants Specialist Report (Forest Service 2022g)
- Wetland and Riparian Resources Specialist Report (Forest Service 2022h)
- Fisheries and Aquatic Habitat Including Threatened, Endangered, Proposed, and Sensitive Species Specialist Report (Forest Service 2022i)
- Wildlife and Wildlife Habitat Including Threatened, Endangered, Candidate, and Sensitive Species Specialist Report (Forest Service 2022j)
- Access and Transportation Specialist Report (Forest Service 2022k)
- Heritage Resources Specialist Report (Forest Service 2022l)
- Recreation Specialist Report (Forest Service 2022m)
- Scenic Resources Specialist Report (Forest Service 2022n)
- Social and Economic Conditions Specialist Report (Forest Service 2022o)
- Special Designations Specialist Report (Forest Service 2022p)
- Tribal Rights and Interests Specialist Report (Forest Service 2022q)
Certain of the environmental resources evaluated in this SDEIS are essentially unchanged from 2020 so specialist reports were not prepared for these resources, which include: geology, hazardous materials, environmental justice, timber, land use, and public health and safety.

3.1.1 Scope of Analysis

For the purposes of this EIS, the term “SGP area” is defined to mean the entire area in which disturbance from the SGP components (i.e., the combined disturbance footprints of the mine site, access roads, utilities, and offsite facilities) for any alternatives would occur.

The analysis area varies by resource or resource use, depending on the geographic extent of the resource or use and the extent of the potential effects of the SGP. In some cases, the analysis area is the SGP area and other cases, the analysis area may be larger or smaller than the SGP area, encompassing administrative or natural boundaries, because the potential effects on the resource can either extend beyond the SGP area boundary or may only occur in a smaller area such as the mine site.

3.1.2 Relevant Laws, Regulations, Policies, and Plans

Each resource section briefly summarizes applicable laws, regulations, policies and plans that pertain specifically to the resource being described and why each is relevant to the resource. This document is prepared pursuant to NEPA, and NEPA and its implementing regulations apply to the evaluation of alternatives and environmental effects with respect to each resource in this document. Further references to NEPA in particular resource sections focus on particular provisions that may apply to that specific resource.

The Payette Forest Plan and the Boise Forest Plan are applicable to most of the environmental resources evaluated and provide guidance on NFS lands in the SGP area. The forest plans have both forest-wide management directions and more specific management area level directions such as Management Prescription Categories (MPCs). These management areas are organized around a combination of watershed and administrative boundaries and are designed to tier to the forest-wide direction to help achieve forest-wide goals and desired conditions.

3.1.3 Existing Conditions

The existing conditions section for each resource describes the potentially affected resources (i.e., physical, biological, social and economic resources or resource uses) qualitatively and/or quantitatively, depending on the analysis requirements identified by the issues and indicators.

The mine site is within terrain consisting of narrow valleys surrounded by steep mountains. Elevations along valley floors range from 6,000 to 6,600 feet amsl. The surrounding mountains reach elevations over 8,500 feet amsl. The main drainage basin at the mine site is the East Fork SFSR. More detailed descriptions of the physical, biological, and social environments are included in the resource sections in the rest of this chapter.
3.2 Geologic Resources and Geotechnical Hazards

3.2.1 Introduction

This section describes the geologic resources and geotechnical hazards at and in the vicinity of the SGP area (Figure 3.2-1). The analysis area for geologic resources includes the footprint of disturbance of all SGP components. Geologic resources as they pertain to this project include bedrock (e.g., ore bodies and development rock) and overburden (e.g., glacially derived sediments, alluvium). Regional geology and seismicity are discussed to provide context to the site-specific features. For purposes of the SGP, the description of existing geotechnical hazards include existing or potential mass wasting features (e.g., landslide, rockfall, avalanche paths) and focuses on the Operation Area Boundary, access road areas, and the areas where the transmission lines would be upgraded and/or new transmission line would be built. In the context of the mine site, geotechnical hazards are described and considered with a focus on three proposed component locations: open pits, the TSF, and the TSF buttress.

3.2.2 Geologic Resources and Geotechnical Hazards Area of Analysis

The geological resources and Geotechnical Hazards analysis area is within the Salmon River Mountains, a high-relief mountainous physiographic province in central Idaho. The Analysis Area consists of the footprint of the proposed SGP disturbance area (as depicted on Figure 2.4-2) where potential impacts to Geologic Resources and Geotechnical Hazards may take place. The generalized geology and project components are shown on Figure 3.2-2.

3.2.3 Relevant Laws, Regulations and Policy

Several laws and implementing regulations apply to the Proposed Action and alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to geological resources and geotechnical hazards.

1872 Mining Law (as Amended) - The statutory right to search for, develop, and extract mineral deposits on federal lands open to mineral entry was established by the Mining Law and later legislation. These rights include the right to initially locate a mining claim and the right to reasonable access to the claim for further exploration, mining, or necessary ancillary activities, consistent with the Mining and Mineral Policy Act of 1970 (30 United States Code [USC] 21a) and other applicable laws.

Paleontological Resources Preservation Act of 2009 - Paleontological resources are managed and protected under the federal Paleontological Resources Preservation Act of 2009 (Public Law 111-11, Subtitle D). The Paleontological Resources Preservation Act defines paleontological resources (with certain exceptions) as “any fossilized remains, traces, or imprints of organisms, preserved in or on the earth’s crust that are of paleontological interest and that provide information about the history of life on earth...” (16 USC 470aaa(4)).

Cave Resources Protection Act of 1988 - Caves and karst formations are protected and managed by the 1988 Federal Cave Resources Protection Act (16 U.S.C § 4301 et seq.).
Mine Safety and Health Act of 1977 - The Mine Safety and Health Act of 1977, as amended (P.L. 91-173 as amended by 95-164) established mandatory health and safety standards for coal and other mines in the U.S. The act and regulations are administered by the MSHA of the U.S. Department of Labor. The MSHA standards and regulations are in Title 30 of the CFR, Mineral Resources, Chapter I. There are federal health and safety standards for all aspects of surface and underground mine operations applicable to: facility designs, methods, equipment characteristics, work practices, inspections, and reporting.

Federal Emergency Management Agency (FEMA) National Dam Safety Program (NDSP) - The FEMA has developed the NDSP, which includes standards that are applicable to structures constructed on federal land, including tailings storage facility embankments (i.e., dams). The NDSP provides a conceptual framework that includes requirements for site investigation and design, construction oversight, operations and maintenance, and emergency planning.

The NDSP is a partnership of states, federal agencies (including Forest Service), and other stakeholders to encourage and promote the establishment and maintenance of effective federal and state dam safety programs to reduce the risk to human life, property, and the environment from dam-related hazards. The NDSP includes federal recommendations for dams related to risk management, emergency action planning, flood risks, design inflows, seismic analysis and design, and general dam safety. The state, IDWR specifically, is responsible for reviewing and approving the design and specifications for TSFs.

Forest Service Mining regulations at 36 CFR 228 - Mining activities on federal land administered by the U.S. Forest Service are regulated under the Forest Service Mining Regulations at (36 CFR 228). Locatable minerals operations such as the SGP are regulated under Subpart A. Large mine operations are required to submit a proposed Plan of Operations describing all aspects of the proposed mine operations.

The regulations at Section 228.8 contain requirements for environmental protection and generally require, where feasible, that environmental impacts to Forest Service-administered resources be minimized. These regulations specifically note requirements related to air quality, water quality, solid wastes, scenic values, fisheries and wildlife habitat, and roads. Section 228.8(c) requires that tailings and other wastes produced by mine operations be handled to minimize adverse impacts to the environment. Section 228.8(g) requires reclamation of areas disturbed in operations to prevent or control onsite and off-site damage to the environment and forest service resources. These rules specifically refer to control of erosion and landslides and isolation or control of toxic materials.

Payette Forest Plan (Forest Service 2003a) and Boise Forest Plan (Forest Service 2010a) - Physical, social, and biological resources on NFS lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. National Forest Land and Resource Management Plans embody the provisions of the National Forest Management Act of 1976 (NFMA) and guide natural resource management activities on NFS land.

In the SGP area, the Resource Management Plans provide management prescriptions designed to realize goals for achieving desired condition for geologic resources and geotechnical hazards and include various objectives, guidelines, and standards for this purpose.
Idaho Department of Lands Rules - Surface mining is regulated by the IDL through the Mined Land Reclamation Act, codified as Idaho Code Title 47, Chapter 15. The Mine Land Reclamation Act requires reclamation of affected land to return them to a productive condition. The IDL regulatory oversight includes mining and other activities on private and patented land, as well as on public lands under federal ownership and/or surface management.

Idaho Department of Water Resources Rules - Idaho dam safety statutes are enumerated in Section 42-1709 through Section 42-1721 of the Idaho Code. Mine tailings impoundment structures greater than or equal to 30 feet high are regulated by the IDWR in the same manner as water storage projects, with an additional provision that a surety bond be secured by the owner, payable to IDWR to ensure the TSF is placed in a safe and maintenance-free condition upon decommissioning.

Idaho Administrative Rules under Idaho Administrative Procedure Act (IDAPA; 58.01.13) - Rules governing mined land reclamation are described in Section 20.03.02 of the IDAPA regulations. Design and construction requirements for Mine Tailings Impoundment Structures are described in the IDAPA Section 37.03.05, while Section 37.03.06 describes rules for the safety of dams. The IDAPA 58 Current Administrative Rules (58.01.13) address ore processing by cyanidation and would apply because these rules are relevant to tailings dams, pipeline, and process ponds if they contain cyanide process water. Idaho Code § 42-1711; Idaho Administrative Procedure Act (“IDAPA”) 37.03.05.40.

Valley County Code - No specific Valley County regulations exist regarding geotechnical issues at mines or geological resources and hazards. However, Valley County has pertinent sections in their ordinances that relates to flood control and land use that may apply to the SGP. Title 11, Chapter 1, Valley County Code of Ordinances.

3.2.4 Affected Environment

3.2.4.1 Geologic Setting

The geological resources analysis area is within the Salmon River Mountains, a high-relief mountainous physiographic province in central Idaho. The legacy mine site has undergone extensive ground disturbing activities associated with past mineral development spanning more than a century (i.e., legacy mining features).

Bedrock Geology, Lithology, and Stratigraphy

Several studies have described the lithologic characteristics and stratigraphy of the intrusive, metasedimentary, volcanic, and unconsolidated rocks exposed in the analysis area. The descriptions that follow are derived from relevant sources as well as from unpublished studies by past operators, Perpetua, and Perpetua contractors and consultants. A regional geologic map of the area is provided in Figure 3.2-1. Figure 3.2-2 provides an overview of general geologic features and rock types in the vicinity of the Operation Area Boundary based on 2007 data available from the USGS. Nomenclature and classification of the rocks in the analysis area has differed over the years by authors. “PC – quartzite” listed on the legend is described in closer detail by others as metasedimentary rock which includes several rock types including quartzite, schist, calcareous schist, and marble. In addition, extent of outlines (contacts) of rock types may differ slightly among references.
Bedrock geology in the region can be subdivided into three generalized groups based on age, lithology, and stratigraphic relationships (listed from oldest to youngest):

- **Pre-Cretaceous to Ordovician**, (greater than 440 million years ago [Ma]), metasedimentary rocks within the Idaho Batholith. These units are exposed in the West End pit and southeast portion of the Yellow Pine pit areas and include a succession of folded, faulted, and metamorphosed carbonate and siliciclastic rocks that comprise a portion of the original rock that was later intruded by the Idaho Batholith and remains as a roof pendant, or mass of original rock that remains after being intruded by igneous rock and projects downward into intrusive rock. Figure 3.2-3 presents a typical stratigraphic column of these materials.

- **Cretaceous** (145 to 66 Ma) igneous rocks of the Idaho Batholith. These rocks host the Hangar Flats deposit and parts of the Yellow Pine deposit and underlie much of the rest of the area. The igneous rocks consist primarily of granodiorite and granite with lesser amounts of diorite and aplite. Nomenclature and classification of the rocks that comprise the Idaho Batholith has differed over the years by authors. In this EIS, the term granodiorite is used synonymously with quartz monzonite to describe the primary rock types of the Idaho Batholith. Intrusive rock nomenclature correlations are described in Gillerman et al. 2019 (Table 2-2).

- **Tertiary** (65 to 1.6 Ma) intrusive and volcanic rocks.

**Surficial Deposits and Features**

In the analysis area, repeated erosional and depositional processes occurred that were associated with glaciation during the Pleistocene. Colman and Pierce (1986) estimated the last glacial advance in the area was approximately 20,000 years ago. Glaciers created U-shaped valleys with over-steepened, talus-covered sides, and hanging-valley tributaries. U-shaped valleys also contain lateral, terminal, and recessional hills and ridges of glacial earth debris, called moraines, as well as glacial outwash deposits at their lower ends.

Alluvial fans are the result of erosion and deposition of material by a stream or river into an adjacent basin. These deposits tend to be fan-shaped in plan view, radiating away from a point source higher up the drainage or valley. Several small alluvial fans in the analysis area have formed over the older glacially derived landforms.

A large alluvial fan occurs below the EFMC (known as the Blowout Creek fan). The failure of a water reservoir earthen dam in 1965 helped create this fan by depositing large amounts of sand and gravel (Midas Gold 2016a, Figure 1). Several coalescing fans also occur at the toe of Garnet Creek (east of the proposed ore processing plant area) and the two smaller drainages to the north. Many of these fans can be and often have been the areas of avalanche runout.

Glacial outwash is glacially derived material that is eroded, reworked by water sourced from glaciers upgradient, and then deposited downstream. Glacial outwash occurs throughout the analysis area and underlies nearly all the larger valley areas.

Modern (Holocene, about 12,000 years ago to present) stream drainage patterns indicate high rates of erosion in the analysis area with coarse-grained sedimentary fluvial deposits in floodplains comprised of a mixture of angular clasts from adjacent bedrock sources combined with more rounded reworked glacial deposits.

**Structural Geology**

The major structural geologic features in the analysis area include Mesozoic folds and Cenozoic faults. Primary references that describe regional geology include Gillerman et al. (2019) and Stewart et al. (2013, 2016).

Folds are a result of pressure on rock causing the rock to bend or fold rather than break. There are multiple fold features in the vicinity of the analysis area including the Tamarack Antiform about 3 miles north of the Yellow Pine pit area (Stewart et al. 2016). Two large map-scale folds with numerous smaller fold structures are known in the Stibnite roof pendant and were first identified as early as the 1920s (Currier 1935; Larsen and Livingston 1920).

The largest fold in the analysis area is the Garnet Creek Syncline, a 3.5-mile-long, northwest-trending syncline (Smitherman 1985; Stewart et al. 2016). A second large fold structure occurs northeast of the Garnet Creek Syncline. It has been informally named the Cinnabar Peak Antiform by Perpetua. The folds in the analysis area are cut by several major fault zones. The most pronounced offsets occur along the Fern Fault in the southeast end of the Stibnite roof pendant and along the Meadow Creek Fault in the northwest end of the roof pendant (Stewart et al. 2016).

A fault is a discontinuity in a volume of rock across which there has been significant displacement as a result of rock-mass movement. Large, north-south striking faults, steeply dipping to vertical structures occur in the central and eastern portions of the analysis area including Meadow Creek Fault Zone (MCFZ); West End Fault Zone (WEFZ); Scout Valley Fault Zone; Garnet Creek Fault Zone; Rabbit Creek Fault Zone; Fern Fault Zone; and Mule Fault Zone. The MCFZ and WEFZ exhibit pronounced fault gouge (finely crushed and ground-up rock) and multiple stages of brecciation, suggesting multiple periods of movement. Available information indicates faults were active over 23 Ma (e.g., Gillerman et al. 2019). These fault zones are poorly exposed, exhibit recessive weathering (surrounding rock is more resistant to weathering than the fault gouge material), and some occur under or along the flanks of the glacially carved valleys.

Regional studies of area fault systems indicate there is a low likelihood of active faults in the analysis area (URS Corporation [URS] 2013) although ground shaking at the Operations Area Boundary caused by earthquakes is possible (URS 2013). The March 2020 Stanley, Idaho earthquake with a magnitude 6.5 and aftershocks occurred southeast of the mine site, about 45 miles west of Challis, Idaho, outside the analysis area. The closest earthquake epicenter to the site in the project-specific earthquake catalog is a magnitude 4.0 earthquake that occurred on August 3, 1963, located about 2.5 miles west-northwest of the SGP.

**Mineralization**

Mineralization in the analysis area began in the late Cretaceous. Hydrothermal alteration is associated with igneous intrusive rocks of the Idaho Batholith and surrounding metasedimentary rocks. Metals
mineralization typically occurs in association with very fine-grained disseminated pyrite and arsenopyrite, with gold almost exclusively in solid solution in these minerals (M3 2019). Antimony mineralization occurs primarily as the sulfide mineral stibnite. Zones of silver-rich mineralization locally occur with antimony and are related to the presence of pyrargyrite, hessite, and acanthite. Coarse-grained stibnite veins are commonly associated with a later stage of mineralization (Gillerman et al. 2019). Tungsten, as the mineral scheelite, occurs as veins and in breccias often intergrown with stibnite, although in many cases scheelite has been observed cemented by or crosscut by stibnite (Midas Gold 2017a).

The alteration that occurred as a result of batholithic intrusion in the Yellow Pine and Hangar Flats deposits is described by White (1940) and Lewis (1984). Gold-bearing mineralization originally occurred as part of multiple phases of hydrothermal replacement. A subsequent high temperature sulfide mineralization phase initially contained little gold but as temperatures decreased, gold-bearing mineralization increased (Midas Gold 2017a).

Regional mapping by the Idaho Geological Survey (Stewart et al. 2013) outlines a previously unrecognized, major, northeast-trending graben complex trending through and just to the southeast of the area (Figure 3.2-2). This feature is likely a fundamental structural control on at least some of the mineralization in the district.

3.2.4.2 Mineral Reserves

The 2021 Feasibility Study prepared for the SGP reports an estimated Proven and Probable Mineral Reserve (the economically mineable part of the measured mineral resource) of 115.3 million tons of ore containing 4.8 million ounces of gold, 6.4 million ounces of silver, and 149 million pounds of antimony (M3 2021). The mineral reserve estimate includes reprocessing approximately 3 million tons of historical mill tailings that underlie the spent leach material in the SODA, which would be mined and used for construction of the TSF.

Yellow Pine Deposit

Mineralization of the Yellow Pine deposit is structurally controlled and localized by the MCFZ and related structures. Gold and antimony have different geochemical signatures, geometries, and locally occurred in different structures during deposition. The deposit shows some apparent zonation with gold occurring throughout the deposit footprint, but with antimony and tungsten primarily in the central and southern portions of the deposit (M3 2019).

The dominant fault directions mapped underground and in the open pits by various geologists from BMC (1938 to 1952), White (1940 to 1941), Cooper (1950 to 1951), and Midas Gold (2012) trend north-south, northeast, and east-northeast. However, the controls for antimony mineralization show more northwesterly trends. The different geometries of antimony and gold distribution suggest different controls for mineralization: antimony is more strongly influenced by northwest fracturing and gold is more strongly influenced by northeast and east-northeast structures.
Historically, 6.48 million tons of ore were mined from the Yellow Pine deposit (Midas Gold 2016a). From the mined materials, 479,517 ounces of gold, 1,756,928 ounces of silver, 40,275 tons of antimony, and 13,579,157 pounds of tungsten were extracted.

**Hangar Flats Deposit**

Mineralization within the Hangar Flats deposit is entirely intrusive-hosted, and structurally controlled and localized by the MCFZ. Past production and currently defined mineralized zones occur along variably north-plunging tabular to pipe-like bodies. The mineralized zones range in thickness from 16 to over 330 feet and can be traced several hundreds of feet down dip. At Hangar Flats, the mineralized zones become thinner, less continuous, and lower grade away from the main MCFZ (M3 2019).

Historically, 303,853 tons of ore were mined from the Hangar Flats deposit, primarily through underground mining (Midas Gold 2016a). From the mined materials, 51,610 ounces of gold, 181,863 ounces of silver, 3,758 ounces of antimony, and 1,062 pounds of tungsten were extracted.

**West End Deposit**

In the West End deposit, gold mineralization occurs preferentially where the northwest-striking, northeast-dipping calc-silicate and schist units are cut by the WEFZ or subsidiary faults, but all rock types host mineralization. Drilling at this location intersected gold mineralization associated with the WEFZ well below the historical pit bottom as deep as 1,300 feet below the original ground surface where mineralization was exposed prior to mining. In addition to sulfide mineralization, open fractures along the WEFZ and subsidiary faults have allowed for oxide formation at depth from meteoric water infiltration (M3 2019).

Historically 8,156,942 tons of ore were previously mined from the West End deposit (Midas Gold 2016a). From the mined materials, 454,475 ounces of gold and 149,760 ounces of silver were extracted.

**Exploration Prospects**

In addition to these mineralized areas, numerous prospects have been discovered during exploration and development activities in the vicinity of the analysis area over the past nearly 100 years. Some of these prospects were developed into mines while others remain undeveloped.

Besides pit expansion possibilities around the main deposits, other exploration targets may one day warrant consideration for development if they can be proved viable after additional exploration, environmental, socioeconomic, metallurgical, engineering, and other appropriate studies. Future proposed mining projects would require analysis and review under NEPA and be required to comply with other federal and state regulations that apply to mining projects.

**3.2.4.3 Legacy Mine Features**

Over 90 years of mineral exploration and development has created numerous prospect pits, shafts, adits, tunnels and underground mine stopes in the analysis area. The locations of former underground and open-pit mine workings have been identified using historic maps and files from legacy operators and
researchers active during operations. The SGP Plan of Restoration and Operations, provides a summary of the history of the Stibnite Mining District and depicts locations (Midas 2016a, Figure 4-2) of previous mining and related activities in the vicinity of the mine site (Midas 2016a).

The analysis area contains piles of rock material from legacy mining and processing activities that includes old development rock piles such as the Bradley dumps, the Meadow Creek Mine dumps, materials excavated and piled near the outlet to the Bailey Tunnel and Clark Tunnel, and material piles near the Yellow Pine pit lake at Monday Tunnel and along the former open-pit benches in the Yellow Pine pit. Tailings were deposited from the 1920s through 1950s in the Meadow Creek drainage and overlain in some areas by spent leached ore (e.g., SODA) in the 1980s and 1990s. Other areas of fill include development rock storage piles at the former Homestake pit, below the current Perpetua exploration camp and shop areas, in West End Creek, and as backfill in the former West End and Garnet pits. There also is a loaded former heap leach pad built, operated, and closed by Hecla Mining in the 1990s, and a series of partially unloaded pads to the east.

3.2.4.4 Paleontological Resources

Potential Ordovician (approximately 485 to 444 Ma) invertebrate fossils were reported by Lewis and Lewis (1982), but later workers, examining the same sites and materials, have determined these are assemblages of alumino-silicate (tremolite) and calc-silicate minerals (Lund 2004; Stewart et al. 2016). The high metamorphic grade and extensive recrystallization of the minerals that make up the sedimentary rock units in the area generally precludes preservation of fossils that would be subject to the requirements of the Paleontological Resources Preservation Act.

3.2.4.5 Cave and Karst Resources

There are no known or suspected cave or karst resources in the analysis area. The extensive metamorphism of the carbonate rocks in the area, as well as level of exposure relative to the original ground surface where caves and karst would form, would generally preclude the existence or preservation of such features in the area.

3.2.4.6 Seismicity

Historic Seismicity

The analysis area is along the western boundary of the Centennial Tectonic Belt (CTB) also called the central Idaho Seismic Zone, which is centered in south central Idaho. Earthquakes with an approximate magnitude of 6 or greater have occurred in the CTB with epicenters east and southeast of the Operations Area Boundary (Figure 3.2-4). The analysis area is within the CTB and has the potential to be subjected to strong (magnitude 6 and greater) earthquake ground shaking from seismic activity related to the CTB feature (URS 2013).
Figure 3.2-4
Quaternary Faults of Central Idaho
Stibnite Gold Project
Stibnite, ID

Figure Source: Golder Associates, Inc.
Several moderate to large earthquakes have occurred in an approximate 60- to 90-mile radius of the analysis area including:

- 1916 Boise Earthquake (magnitude 6)
- 1944 and 1945 Seafoam earthquakes (magnitude 6.1 and magnitude 6.0, respectively)
- 1983 Borah Peak earthquake (magnitude 6.9)
- 1993 White Cloud Peaks earthquake swarm (highest single earthquake magnitude 5.1)
- 2020 Stanley earthquake (magnitude 6.5) (USGS 2020b)

These earthquakes occurred near the center of the CTB (approximately 30 miles southeast of the analysis area) (URS 2013, USGS 2020b, Golder 2021). The most significant potential seismic sources near the analysis area include the Cascade, Council, Deadwood-Reeves Creek, Long Valley, and Sawtooth fault zones (Golder 2021) (Figure 3.2-4).

Although numerous faults are present within the analysis area, none show evidence of recent active movement nor do historic records suggest this has occurred. However, shallow mass slope movements related to weathering and typical slope processes in mountainous terranes (e.g., slumps, debris slides, avalanches) do occur, and activation of these features during a strong seismic-induced ground shaking event is possible (URS 2013).

**Seismic Hazard Analysis**

A seismic hazard analysis describes the natural phenomena such as ground rupture, fault movement, or soil liquefaction that could be caused by an earthquake. The purpose of the analysis is to determine the magnitude of ground accelerations due to various earthquake events to be used in the stability analysis. The results of seismic hazard analysis are used as a basis for design and mitigation measure decisions (FEMA 2006). An initial site-specific seismic hazard analysis (SHA) was conducted by URS (2013). In conversations with the IDWR, Perpetua was advised to update the SHA for the SGP. The update was prepared by Golder Associates Inc. in May 2021 (Golder 2021).

The updated SHA incorporated technical developments in SHA methodology since 2013 and utilized updated seismic source (earthquake) records from the USGS national seismic hazard map in 2014, 2018, and data from the March 2020 earthquake near Stanley, Idaho. Golder revised the list of faults considered in the SHA by URS (2013) to delete one small fault and add four large faults. The nine major crustal faults within 62 miles of the SGP that were considered in the Golder analysis included: Deadwood-Reeves Creek, Long Valley, Sawtooth, Council, Shirt Creek, Rush Peak, Lost River-Challis Section, Lost River-Challis /Warm Springs/Thousand Springs Sections, and Squaw Creek. Of these, the Deadwood-Reeves Creek fault was the closest to the SGP site at a geometric distance of about 5.3 miles.

In addition to the updated seismic source information Golder incorporated the updated earthquake acceleration attenuation ground motion models (GMMs) applicable to this part of western North America.

The seismic hazard is assessed from instrument measurements as well as historical accounts and geologic observations. SHA is quantified by three parameters: level of severity, spatial measurement, and temporal measurement (Wang 2009). The seismic hazard was assessed for the SGP site including the proposed
Stibnite Gold Project Supplemental Draft Environmental Impact Statement

TSF location, but the results are also usable for the other proposed facilities at the SGP. Golder performed both probabilistic and deterministic seismic hazards analyses. The combined results, probabilistic SHA (PSHA) and deterministic SHA (DSHA), are an effective means for determining maximum design earthquake ground motions. Maximum design earthquake is an earthquake that would produce the maximum level of ground motion (shaking) for which a structure (e.g., TSF dam) is to be designed or evaluated (FEMA 2005).

PSHA is used to determine the likelihood (probability of occurrence) that a given level of ground shaking could be exceeded during a specified timeframe at a site from a combination of earthquake sources. The likelihood of exceedance is determined by the probability of occurrence of any earthquake with a range of magnitudes, typically within about 62 to 125 miles of the selected site. The analysis includes consideration of the attenuation of ground motion from the earthquake sources to the site. Empirical GMMs are used to model the ground motion attenuation rate for any given earthquake magnitude, source-to-site distance, and site ground conditions.

Peak ground acceleration (PGA) is traditionally used to quantify ground motion (shaking) at a site and is generally a function of the magnitude of the event and distance from the source, but other factors may be considered, such as rock type or type of faulting. The PGA is typically expressed in terms of a fraction of gravity (g), with probability of exceeding a certain level over a specific period of time.

The PSHA results for the URS analysis indicated the PGA for 475-year and 2,500-year return period earthquake events are 0.06g and 0.14g, respectively. The Golder analysis indicated comparable PGA estimates of 0.075g and 0.18g for the same return periods, respectively. For context, a PGA of 0.1g in bedrock is considered the approximate threshold at which damage occurs in buildings that are not specially constructed to withstand earthquakes (FEMA 2006).

DSHA is based on known regional seismic sources and, unlike the PSHA, does not consider the probability associated with a particular earthquake hazard. In a DSHA, the ground motions at the site are estimated for the maximum credible earthquake that could impact the site. For the URS (2013) analysis the maximum credible earthquake modeled was a magnitude 6.9 earthquake on the Deadwood-Reeves Creek fault (URS 2013). This event was estimated to result in median calculated PGA of 0.43g at the SGP site. The Golder analysis was based on a maximum credible earthquake of magnitude M7 on the Deadwood-Reeves Creek fault which resulted in an updated PGA of 0.32g at the SGP site (Golder 2021). Golder explained the main reason for the differences in estimated PGAs at the site was that URS used the NGA-West1 Project GMMs available at the time (2013) and Golder used the updated NGA-West2 Project GMMs (Golder 2021).

Final design of the SGP TSF and other facilities would incorporate the site-specific ground accelerations calculated from the latest seismic hazard analysis.

The Golder (2021) SHA results are similar to those of the USGS National Seismic Hazards Maps (NSHMs) which are the basis for the U.S. building code provisions and the International Building Code. The Golder results are less than, or about the same, as the 2014 USGS NSHM but larger than comparable hazard values in the USGS 2018 NSHM.
3.2.4.7 Foundation Characterization and Mass Wasting Hazards

Mass wasting or geohazard features in the Operations Area Boundary mine area and access roads can be classified in landslides or rockfalls and snow avalanches.

“Landslide” is a general term used to describe the downslope movement of soil, rock, and organic materials, or a combination thereof, under the effect of gravity. The term landslide also describes the landform that results from such movement (Highland and Bobrowsky 2008). Landslide types include rockfalls, deep-seated slope failures, mudflows, debris flows, and slumps. Debris flow is a mass of soil and/or fragmented rock in slurry of water that moves downslope under the influence of gravity and forms muddy deposits in valley floors. Slump as defined for the EIS: Geohazard assessment reports (STRATA 2013, 2014a, 2016) use the term “slough” and “slump” interchangeably to refer to “small landslides” of less than 0.1 acre. For purposes of consistency, this EIS uses the term “slump” in the text. However, figures originating from the referenced geohazard assessment report may still retain the use of “slough.”

Many of the very large landslides in the area are likely post-glacial features. During glaciation large chunks of ice may become buried in glacial till. When the ice melts after glaciation, the materials can become unstable, resulting in large landslides. Some of the larger geohazards features depicted on Figure 3.2-5 may have occurred through this process. An example is the landslide identified on the east side of the East Fork SFSR north of the camp area (STRATA 2014a).

An "avalanche" is a slope failure composed of a mass of rapidly moving, fluidized snow and ice that slides down a mountainside. After initiation, avalanches usually accelerate rapidly and grow in mass and volume as they entrain more snow and ice. Avalanches can pick up debris from the ground, including soil, rock, large boulders, and trees.

Avalanches occur on slopes averaging 25 to 50 degrees, with the majority on slopes between 30 and 40 degrees, and several avalanche hazard areas occur within the analysis area (Figure 3.2-5). Avalanches are triggered by natural seismic or climatic factors such as earthquakes, thermal changes, rainfall, and blizzards, or by human activities (Idaho Office of Emergency Management 2018).

The most common types of avalanches are loose-snow and slab avalanches. A loose-snow avalanche is composed of dry, fresh snow deposits that accumulate as an unstable mass atop a stable snow and slick ice sublayer. A loose-snow avalanche releases when the sheer force of its mass overcomes the underlying resistant forces of the cohesive layer. A slab avalanche generally is composed of a thick, cohesive snowpack deposited or accumulated on top of a light, cohesion-less snow layer or slick ice sub-layer. At the starting surface or top of the slab, a deep fracture develops in the slab of well-bonded, cohesive snow. A slab avalanche release is usually triggered by turbulence or impulse waves.

Operations Area Boundary

The following subsections describe the geology and known landslide and avalanche hazards in the vicinity of the Operations Area Boundary based on geologic hazard assessments (STRATA 2014a, 2016) and an Avalanche Hazard Assessment for portions of the Operations Area Boundary (Mears and Wilbur...
Engineering 2013). **Figure 3.2-5** shows landslide and rockfall (slope failure comprised of rock) features in the vicinity of the SGP, as well as avalanche paths within the central Operational Area Boundary area.

Geologic and geotechnical conditions have been well characterized at the Operations Area Boundary by information derived from several studies conducted over multiple field seasons. Studies included drilling, sampling, and logging boreholes, standard penetration tests, cone penetrometer tests, geotechnical laboratory tests (e.g., particle size distribution, Atterberg limits, direct shear), groundwater monitoring wells, piezometers, aquifer slug tests, as well as specific structural geology investigation and a pit slope design study. A comprehensive discussion of available geologic information is provided in the SGP Geotechnical Investigations Summary Report (Tierra Group 2018), the Geotechnical Baseline Summary (STRATA 2017; Tierra Group 2017), and the SGP Feasibility Study Technical Report (M3 2021).

Structural orientations of faults and joints were measured at rock exposures as well as the width, infill, and kinematic indicators, if present. In addition to examination of surface exposures, oriented boreholes were drilled in the Yellow Pine pit, West End pit, and Hangar Flats pit areas and continuous rock core was sampled (Tierra Group 2018).

Several studies were performed to evaluate pit slope design (STRATA 2014b). The STRATA (2014b) study found that the rock at all three pits consisted predominately of quartz monzonite and quartzite. These rock types are typically very competent.

The SGP Comprehensive Baseline Geochemical Characterization Report (SRK 2021a) provided combined results of Phase 1 and Phase 2 rock geochemical characterization programs and the overall conclusions of the updated characterization were not changed from the 2017 reporting.

The SGP Geotechnical and Geophysical Data Evaluation Memo (Brown and Caldwell 2022a) describes statistical analyses of core structural characteristics and also shallow seismic surveys completed in 2017. This information described a widespread bedrock condition in the SGP area where the upper portion of the bedrock directly underlying unconsolidated materials was more weathered and fractured than the underlying, more competent bedrock.

**Northern Area: Yellow Pine and West End Pits**

The terrain in the northern Operations Area Boundary is relatively steep with natural timbered slopes as steep as approximately 31 degrees (1.67H:1V). Waste rock disposal areas from previous mining activity are northeast of the historic Homestake pit (the site of northeastern end of proposed Yellow Pine pit) and to the southeast of the historic West End pit.

Observed overburden thickness in the area northwest of the planned Yellow Pine pit ranges from 47 to at least 180 feet, and depth to bedrock generally increases toward the west. The uppermost material in boreholes drilled approximately 2,000 feet to 750 feet northwest of the outline of the Yellow Pine pit consists of development rock from legacy mining activities (STRATA 2017; Tierra Group 2017). Native soil beneath the development rock is mostly sand, with some gravel. Overburden depth in the valley bottom area south of the Yellow Pine pit ranges from 47 to 61 feet and consists mostly of sand and gravel, with occasional layers of silt noted in the borehole logs. Side slopes to the west have thicker overburden, up to 200 feet thick, composted of glacial outwash materials.

The predominant structural feature in the Yellow Pine pit area is the MCFZ, which generally is north-northeast striking and steeply dipping to the west or northwest. Associated with the zone are north-striking, west-dipping conjugate splay or cross structures. The widest recognized section of the fault zone is about 190 feet wide. Other faults in the area tend to be sub-parallel to the MCFZ; these include the Hennessy Fault, Hanging Wall Shear Fault, C-Shear Fault, Meadow Creek Hanging Wall Fault, and Meadow Creek Footwall Fault.

Eleven boreholes, ranging in length from 56 to 695 feet, were drilled along the East Fork SFSR tunnel alignment during multiple investigations, and additional overburden and bedrock boreholes were drilled nearby for Yellow Pine pit exploration and geotechnical investigations to aid interpretation of subsurface conditions. Overburden near the proposed tunnel portals consists of legacy development rock and native glacial till ranging in grain size from silt through boulders. Depth to bedrock was 55 to 136 feet. Bedrock along the tunnel alignment is generally unaltered to weakly altered and weakly mineralized. Hennessy Shear Zone and MCFZ displayed fractured intrusive rock, with zones of gouge and breccia. Four seismic refraction geophysics lines were completed at the portals to define the bedrock profile.

A full description of these geotechnical investigations, stratigraphy, rock mass characterization, and geophysics is provided in the Geotechnical Investigations Summary Report (Tierra Group 2018) and East Fork SFSR Tunnel Design Documentation Report (McMillen Jacobs 2018).

The Yellow Pine backfill is wholly within the Yellow Pine pit and would be underlain by bedrock. Yellow Pine backfill would be placed within the Yellow Pine pit long after overburden is removed from the area. Fifteen boreholes were completed in this area during multiple investigations, including five boreholes to classify the rock mass (no overburden geotechnical data was collected for these five boreholes).

The predominant structural feature in the West End pit area is the WEFZ, which generally is striking north-northeast and steeply dipping southeast, and includes the Hanging Wall, Middle, and Footwall faults.

Two slumps, four landslides, and a rockfall are noted in this area (Figure 3.2-5). The isolated slumps likely were caused by oversteepening of the slope due to road cuts and the presence of groundwater seepage near or at the ground surface. Potential rockfalls are primarily related to former open-pit mining slopes in the Homestake pit, West End pit, and the Stibnite pit.

The Avalanche Hazard Assessment (Mears and Wilbur Engineering 2013) did not include an assessment of avalanche hazards in the vicinity of the proposed Yellow Pine and West End pits.

Central Area: Mine Support Facilities

The central area extends south of the Yellow Pine pit and encompasses most of the proposed mining support facilities in or adjacent to the East Fork SFSR valley floor, a relatively flat area. Geologic materials are comprised of alluvium, glacial deposits, and ancient landslide deposits (STRATA 2013).

Twenty-four geotechnical boreholes and groundwater monitoring wells were completed at the area of the ore processing facility and proposed Scout exploration decline during multiple investigations. Native soils
consist of alluvial and colluvial sands and gravel. Bedrock was encountered at depths ranging from 5 to 97 feet below ground surface.

Potential geohazards identified in the Central Area are shown on Figure 3.2-5 and include two slumps, one landslide, three rockfalls, and three areas with groundwater seeps.

Two relatively small slumps occur in old road cuts along a now obscured former access road. The other slump is just north of the first slump. Groundwater seeps suggest that seeps and elevated groundwater may have helped initiate these slope failures (STRATA 2014a).

A larger landslide covers several acres to the east of the East Fork SFSR and is believed to be a post-glacial landslide. A groundwater seep also occurs near the south margin of the landslide.

Directly behind and to the east of the core building at the exploration camp is a rock outcrop producing a rockfall comprised of angular cobbles and small boulders. The hill slope to the west of the confluence of Meadow Creek and the East Fork SFSR has large steep outcrops of quartz monzonite that could produce rockfalls (STRATA 2014a).

Mapped avalanche paths in this area are mostly on the slopes to the east of Meadow Creek. Some are mapped between the proposed cell tower access road and new transmission line segment (Figure 3.2-5) (Mears and Wilbur Engineering 2013).

Southwest Area: Hangar Flats Pit and SODA

The southwest area is within the relatively flat valley floor of Meadow Creek. The area is the proposed location for the Hangar Flats pit. The SODA is currently upstream from the former Hecla heap leach pad in this same terrain.

Exploration drilling in the Hangar Flats area indicates that depth to bedrock increases greatly with distance from adjacent valley slopes, suggesting a deep U-shaped valley, filled with stream sediments overlying glacial deposits. Overburden thickness is greatest in the south-central area, where the depth to bedrock was noted to be more than 250 feet (borehole SRK-GM-22S). Surficial soils were moderately dense to dense sands with some gravel and occasional silt layers. Beneath the surficial layers, the soils are mostly sand and gravel inter-bedded with silty sand. At depths greater than 200 feet, clayey sand and clayey gravel were encountered.

The predominant structural feature in the Hangar Flats area is the MCFZ, which generally is north-striking and steeply dipping (nearly vertical). Associated with the zone are northeast or east-trending, nearly vertical conjugate structures. Splays of the MCFZ are common and trend northeast, with shallow dips to the northwest. The MCFZ is a broad structural zone, marked by intense shearing, characterized by fault breccia and gouge.

Based on reconnaissance and helicopter fly-over observations, five landslides were identified in this area by STRATA (2014a) (Figure 3.2-5). A narrow (about 200 feet wide) debris flow scar originates near the Meadow Creek Mine portal and extends downslope to the valley floor. Another narrow landslide area is in a shallow drainage on the north hillside near the west end of the SODA.
A slow-moving landslide (i.e., creep) of approximately 20 acres is in the mouth of the drainage above the west end of the Hecla heap leach site. The toe of the landslide is near the projected toe of the TSF Buttress.

Two landslide features occur on the northwest-facing hill slope to the south of the Meadow Creek confluence with East Fork SFSR and extending to the mouth of Blowout Creek. One is characterized by irregular hummocky ground and seeps indicate past landslide activity covering approximately 80 acres. A smaller slump in a road cut is present about half-way downslope and to the west. This slump area appears to be several years old and has been treated with staked erosion control matting; new vegetation is established in the scar.

The majority of the SODA and the proposed TSF Buttress are within mapped avalanche hazard zones (Figure 3.2-5) (Mears and Wilbur Engineering 2013).

Southeast Area: East Fork SFSR and Worker Housing Facility

The terrain in southeast area is primarily in or adjacent to the valley floor of the upper reaches of the East Fork SFSR and is relatively flat.

Seven boreholes were completed at the Worker Housing Facility area during multiple investigations. Native soils consist of alluvial and colluvial sands and gravel. Bedrock was encountered at depths ranging from 23 to 39 feet below ground surface, but four boreholes were not advanced to bedrock.

Landscape features are dominated by glacial deposits, particularly lateral moraines and a large ancient landslide on the south hillside of the drainage, approximately 1 mile upstream of the confluence of the East Fork SFSR and Meadow Creek (STRATA 2014a). Two landslides were identified in this area in addition to two areas that were observed with seeps, indicating a potential for future slides.

A large, ancient (glacial age) landslide covers at least 200 acres south of the East Fork SFSR and appears to have dammed the drainage in the past, likely forming the depositional area that is now a flat meadow. This area is characterized by hummocky ground and local areas of seeps, or wet areas with spongy ground.

There also is an ancient landslide of about 9 acres upslope of the proposed worker housing facility in the East Fork SFSR valley about 1.3 miles upstream from its confluence with Meadow Creek. Thunder Mountain Road (FR 50375) crosses the central portion of this feature just east of the flat floodplain area.

Avalanche hazard zones have been identified in Rabbit Creek valley and the adjacent unnamed stream valley to the southeast, as well as directly east of the proposed worker housing facility. Additional avalanche hazards zones are mapped near the northernmost Burntlog Route borrow source (Mears and Wilbur Engineering 2013).
TSF Buttress

Eighty-six boreholes were drilled at the proposed TSF Buttress area during multiple investigations, with 42 of these boreholes specific to the SODA. Native soils generally consist of alluvial and colluvial sands and gravel. Bedrock was encountered at depths ranging from 90 to 180 feet below ground surface. Up to 75 feet of spent ore, and 55 feet of Bradley tailings were encountered.

Three borings were drilled at the proposed TSF Buttress and Hangar Flats pit footprint area to characterize the rock mass (Tierra Group 2018). The Hangar Flats pit geotechnical information is applicable to this area.

A full description of these geotechnical investigations, stratigraphy, and laboratory testing is provided in the Geotechnical Investigations Summary Report (Tierra Group 2018).

Effects of Legacy Underground Mine Openings

The first phase of large scale (mostly underground) mine development of the SGP area commenced in the 1920s and continued into the 1950s. This ore was processed in local mill and smelter facilities. The second period of major mining activity in the area commenced with open pit mining and heap leaching from 1982 to 1997. The open pits, development rock disposal areas, mill tailings, and spent heap leach materials resulting from these legacy mine operations are evident on the ground surface of the SGP property. The underground mine developments are not as obviously present and are discussed below. The descriptions of these mine operations were obtained from Victoria Mitchell's History of the Stibnite Mining Area (Mitchell 2000), and the 2021 Feasibility Study Technical Report (M3 2021).

The Hangar Flats deposit was mined underground between the 1920s and 1937 in what was known as the Meadow Creek Mine. The mine was developed on six levels with numerous drifts and crosscuts (tunnels), raises and winzes (underground shafts), and stopes (irregular openings where ore was removed). The mine openings were reinforced with wood supports and the exhausted stopes were backfilled with development rock. In addition to two Meadow Creek Mine adits, two other tunnels were driven toward the deposit from the north, including the North Tunnel in the Fiddle Creek Gulch and the Monday Tunnel along the lower East Fork SFSR. About 25,426 feet of underground workings were developed in the Meadow Creek Mine during this period. A small amount of additional ore was removed from the mine in the early 1940s from two levels of the mine that were not caved or flooded. Between 1951 and 1954, the Defense Minerals Exploration Administration (DMEA) carried out an underground exploration program immediately north of the Meadow Creek Mine that resulted in about 4,900 feet of underground workings on three levels.

The Yellow Pine Deposit claims were first staked in 1923 and explored with two short tunnels. The property was optioned to F.W. Bradley's Yellow Pine Mining Company in 1929 which did exploration of the Yellow Pine deposit in five tunnels and drove the Monday and Cinnabar tunnels on opposing sides of the valley. The Cinnabar Tunnel headed toward the east to explore and develop the Cinnabar Claim Group and the Monday Tunnel was driven over 6,000 feet south along the Meadow Creek Fault Zone to intercept the Meadow Creek Mine at its 400-foot level but stopped short of this goal. After the Meadow Creek Mine shut down, mining activities shifted in earnest to the Yellow Pine area with both open pit and
underground exploration and production between 1938 and 1952. Two shafts were sunk from the surface and three underground levels were developed with a winze (underground shaft) leading to the deepest level. Approximately 4,000 feet of underground workings (drifts, crosscuts, and stopes) were developed with the openings supported by timber sets. Exhausted stopes were backfilled with glacial till obtained from the surface overburden stripping. The decision was made in the early 1940s to increase production with open pit mining methods. In 1943 flow in the East Fork SFSR was routed around the Yellow Pine pit in the 3,500-foot-long Bailey Tunnel that collected the stream on the south side of the pit and discharged to Sugar Creek north of the pit. Between the late 1940s and 1952 all ore production from the Yellow Pine Mine was from the open pit operations which intercepted some of the former underground mine openings.

The legacy mine and heap leach disturbances from past surface mining activities in the Yellow Pine, Hecla, and West End open pits are not the subject of this discussion of the impacts of the underground mine openings on the 2021 MMP and will not be further discussed here.

The proposed Hangar Flats and Yellow Pine pits would intersect legacy underground workings and have been designed with this in mind. The locations of the above-described underground workings are shown on Figure 2.4-17 along with the proposed boundaries of the Hangar Flats and Yellow Pine pits.

In the 2021 MMP (Perpetua 2021a), the Hangar Flats pit has been reduced by 70 percent compared to the 2016 configuration (Midas Gold 2016a). One of the reasons contributing to this reduction, as noted in the 2021 Feasibility Study (M3 2021), is “a number of technical challenges, risks, and costs associated with mining through the extensive historical underground workings”. As shown on Figure 2.4-17, most of the Meadow Creek Mine underground workings underlie the proposed Hangar Flats pit. Perpetua’s mine engineer also notes that a double-wide catch bench (40-foot instead of 20-foot) is incorporated into the Hangar Flats pit design to partly account for some potential wall instability in the vicinity of underground workings (Perpetua 2021f).

The tunnels to the north of the main Meadow Creek Mine underlie the high mountain slopes to the west of the East Fork SFSR and would not underlie any of the proposed mine operations facilities. All of the Meadow Creek Mine underground workings and connected tunnels are not located under any of the proposed support facilities including the truck shops, mill complex, worker housing, TSF Buttress, or TSF embankment or impoundment.

The Yellow Pine pit would intersect portions of several tunnels, drifts, and stopes of the former Yellow Pine Mine underground workings, including portions of the Monday Tunnel and the Bailey Tunnel, and would completely mine through underground workings of the Yellow Pine Mine (Figure 2.4-17). Intersecting these features is not anticipated to result in stability concerns. The Monday Tunnel/Yellow Pine pit wall intersection would approximate the tunnel cross-sectional diameter as the pit wall would be nearly perpendicular to the tunnel axis. Similarly, much of the Bailey tunnel would be excavated by mining activity and the remaining pit/tunnel intersection would be nearly perpendicular to the final pit wall, leaving a remaining opening into the pit wall approximately 6 feet in diameter (Perpetua 2021f).

Expressions of legacy underground workings located below the ultimate pit backfill levels would be blocked/filled with development rock to prevent public or wildlife access prior to pit backfilling.
Expression of legacy underground working located above ultimate pit backfill levels would be closed in a manner similar to the East Fork SFSR and Scout Decline tunnels as described in Section 2.4.7.3.

**Access Roads**

To identify mass wasting hazards along the Burntlog Route and the Johnson Creek Route Alternative, the following information sources were used to evaluate risks:

- Avalanche hazard mapping was completed for the Operations Area Boundary and the final 2.5 miles of the Burntlog Route into Stibnite mine by Mears and Wilbur Engineering (2013).
- STRATA (2016) conducted a survey of geologic hazard conditions along the proposed Burntlog Route access road which mapped areas impacted by rockfalls, landslides, and wet soils.
- DAC (2018) reported on potential snow avalanche hazards affecting the Burntlog Route, including several alternatives that were under consideration at that time.
- The Warm Lake Summit area was included in the DAC (2018) mapping, as well as the Operations Area Boundary mapping completed by Mears and Wilbur Engineering (2013).
- DAC (2021) updated the avalanche mapping and risk analysis for the proposed and alternative access routes.

AECOM (2020c) conducted a study to identify probable landslides, rockfalls, and avalanche paths along the Burntlog and Johnson Creek routes based on 2020 aerial imagery and using the observed vegetation signatures, substrate color, erosion evidence, and slope calculations. Landslide and rockfall hazards were identified along existing road cuts based on vegetation signatures and evidence of migrating slope failures upslope of the road prism. Rockfall hazards were identified along existing road cuts based on vegetation signatures, substrate color, and evidence of slope erosion upslope of the existing road prism. Information from STRATA (2016) was considered along both existing and proposed roads. Snow avalanche paths were identified based on vegetation signatures and supplemented with slope calculations and compared to other data from the prior reports described above.

Hamre (2021) reported on both the Burntlog Route and the existing Stibnite Road portion of the Johnson Creek Route up the East Fork SFSR from the village of Yellow Pine. That work included evaluation of methods of avalanche risk reduction with associated costs and presented avalanche path mapping for the larger avalanche paths that affect Stibnite Road.

The avalanche mapping presented by DAC (2021) included detailed avalanche path descriptions for the Stibnite Road, Johnson Creek Road, and the Cabin Creek to Trout Creek snowmobile route. The Mears and Wilbur Engineering (2013) mapping was not modified because it was completed at a higher level of detail and field investigation (i.e., hazard zoning [Blue and Red]) for facilities. Any new or modified avalanche paths mapped by Hamre (2021) were considered and (in most cases) included as part of the DAC mapping. The DAC (2021) avalanche descriptions were comprehensive and included consideration of terrain factors including: elevation, vertical fall height, slope incline, aspect (direction that the starting zone faces relative to solar exposure and prevailing wind directions), terrain shape (concavity or convexity downslope and across slope), surface roughness, and vegetation cover (e.g., forest cover and tree density). Potential snowfall and snowpack depth amounts varied by elevation and geographic...
location. These variables were evaluated to assess the potential magnitude and frequency of avalanches expected to affect the roads at each path. DAC also described the miles of road potentially affected by the avalanche paths, potential frequency of avalanches (low to high), range of frequency in years, likely size of the avalanche at the road (D2 to D4), and descriptive comments of the potential avalanches.

Very small (D1, < 10 tonnes of snow mass) sized avalanches that would not present a risk to vehicles on the roads were not mapped. Small (D2, 100 tonnes of snow) that could be operational hazards to traffic were described, as were paths of D3 (1,000 tonnes of snow) sized avalanches that could bury or destroy a car. Only a few D4 (10,000 tonnes) sized avalanche paths were identified, located above the Stibnite Road. These large avalanches could destroy large trucks and a substantial amount of forest.

The Transportation Management Plan (Perpetua 2021e) shows the locations and extent of geologic hazards and avalanches described in the above referenced study reports for both transportation routes. That same information is shown on Figure 3.2-6.

**Burntlog Route**

Landslide and rockfall hazards have been assessed along the Burntlog Route, including in-field observations (STRATA 2016). Visual evidence of slope instability was reported at several locations along the route. Potential rockfall areas are primarily tied to existing road cuts occurring in both glacial till/colluvium and granitic outcrops.

Avalanche paths were comprehensively described by DAC (2021) for the overall Burntlog Route. Along the existing road from Warm Lake to Landmark they identified 11 avalanche paths potentially affecting 1.6 miles (Figure 3.2-6). These were relatively high frequency avalanche paths (1 to 3 years) producing small (D2), loose avalanches with two larger (D3) avalanche paths that could affect the road about every 3 years.

Along the existing Burntlog Road from Landmark to the ridge above Black Lake, seven D2 sized avalanche paths were identified potentially affecting 0.5 miles of road with four of them having the potential to affect the road on average every 10 years.

From the end of the existing Burntlog Road to Stibnite, 20 avalanche paths were identified along the alignment of the proposed extension of the Burntlog Road potentially affecting 2.4 miles of road. Most of these were D2-sized paths with high frequencies (1 to 3 years). There were two potential D3 paths with moderate frequencies (3 to 10 years).

A total of 38 avalanche paths were identified by DAC (2021) along the Burntlog Route from Warm Lake to Stibnite potentially affecting 4.5 miles of road (Figure 3.2-6).

**Johnson Creek Route**

The Johnson Creek Route includes Johnson Creek Road (CR 10-413) and Stibnite Road (CR 50-412). Identified geologic hazards, including those based on the desktop study are depicted on Figure 3.2-6. There is documentation of avalanches and landslides along this route (Midas Gold 2019a). In March 2014, a series of avalanches blocked Stibnite Road (CR 50-412) in two locations and caused the river to
reroute onto the road. In April 2019, a series of avalanches and related landslides caused extensive
damage to Stibnite Road (CR 50-412), resulting in closure of the road for approximately two months. The
slides pushed snow, timber, and other debris into the East Fork SFSR and up onto Stibnite Road, and
sections of the road near Tamarack Creek were washed away.

Avalanche paths were comprehensively described by DAC (2021) for the overall Johnson Creek Route.
The portion of the route from Warm Lake to Landmark is common with the Burntlog Route and is
described above. The 11 avalanche hazards affecting 1.6 miles of road for that segment are included in
the totals for the Johnson Creek Route.

Avalanche terrain along Johnson Creek begins approximately 10.5 miles north of Landmark. From that
point north to Yellow Pine, 20 avalanche paths were identified potentially affecting 2.4 miles of the
Johnson Creek Road. Most of these paths were at relatively lower elevations and were small sized.
Consequently, all paths along Johnson Creek Road were assessed to potentially produce D2-sized
avalanches with frequencies of 10 to 30 years and some of the same paths could produce D3-sized
avalanches with 30- to 100-year frequencies.

In the 13.5 miles from Yellow Pine to the north end of the SGP mine site, a total of 63 avalanche paths
were identified potentially affecting 4 total miles of road, 2.6 miles of which were likely to produce D2-
or D3-sized avalanches with low to high frequency (1 to 30 years) and 1.4 miles of which were likely to
produce D2- to D4-sized avalanches with low to high frequency that could cause damage to Stibnite Road
as documented in 2014 and 2019.

Avalanche paths across the East Fork SFSR have the potential to deposit snow and forest debris into the
river and on the road. Avalanches in this area can also create dams which could then cause scouring of the
riverbanks and damage the road.

Near the confluence of the East Fork SFSR and Tamarack Creek, about 6 miles from Yellow Pine, is a 2-
mile length of the canyon containing a total of 27 avalanche paths affecting 1.4 miles of road that is
almost continuously exposed to D2 and D3 avalanche paths that could impact the road with a 1- to 3-year
return period. These include five paths with the potential for producing D4-sized avalanches with a
frequency of 30 to 100 years, presenting a large hazard to traffic, and could severely damage the road
itself. A large amount of standing dead timber remains in these paths that could be entrained in these
avalanches.

A total of 94 avalanche paths were identified by DAC (2021) along the Johnson Creek Route from Warm
Lake to the SGP potentially affecting 8 total miles of road (Figure 3.2-6).
Figure 3.2-6
Identified Geohazards Along Burntlog and Yellow Pine Access Routes Stibnite Gold Project Stibnite, ID
Proposed Cabin Creek to Trout Creek OSV Route

The OSV Route was assessed for avalanche hazards by DAC (2021) to aid with managing this route during the winter months with respect to avalanche hazards. It was assumed that snowmobilers would follow the proposed alignment, which mostly follows an existing forest service road. Deviating from this alignment closer to either side of the valley could expose snowmobilers to a higher avalanche hazard. Like Warm Lake Summit, the OSV Route receives higher precipitation than other parts of the project area, which is expected to result in higher avalanche frequency than drier areas to the northeast.

A total of 18 avalanche paths potentially affecting 1.6 miles of the road were identified by DAC (2021) along the proposed OSV route (Figure 3.2-6). The relatively high snowfall along this route suggests that most of these paths are expected to produce D2-sized avalanches on an annual basis with potential D3 avalanches with a 10- to 30-year return period.

Summary of Geohazards and Avalanches along the Proposed Access Road Alternatives

3.3 Air Quality

3.3.1 Introduction

This section describes the area of analysis for air quality, applicable government requirements, and the baseline, or affected environment of the SGP area. Additional details may be found in the Air Quality Specialist Report (Forest Service 2022a).

3.3.2 Air Quality Area of Analysis

An air quality analysis usually relies on defined geographic regions that represent the areas for which different types of modeling would be conducted. First, a “near field” was examined using appropriate models to quantify the effects of action alternative sources. The near-field modeling domain for the ambient air quality analysis, which extends 10 km from the SGP, is depicted in Figure 3.3-1. Other aspects of the near-field modeling such as nitrogen and sulfur deposition used a domain of 50 km from the SGP. Federal modeling rules (40 CFR 51, Appendix W) stipulate that near-field models may be applied for distances of 50 km or less from the emission sources. For the SGP, preliminary modeling
confirmed that the 10-km domain size was adequate to characterize near-field air quality impacts. Air quality effects would typically decrease at distances beyond the modeled 10 km range.

The refined model uses a “grid” of defined receptor points at which air pollutant concentrations are predicted by the model calculations. Receptor tiers were used starting at 25 m along the Operations Area Boundary and transitioning to 1 km spacing out to the 10-km extent of the modeled domain to follow accepted regulatory modeling practice. Tighter spaced receptors were used closer to the Operations Area Boundary to allow the model to map in more detail the predicted close-in concentrations that are generally the highest.

Second, a much larger “far-field” region was defined within an area up to 300 km-radius from the SGP that encompassed more-distant Class I areas, wilderness areas, Tribal reservations, and other areas requested by Tribes were considered in the analysis. For the SGP, this region is shown in Figure 3.3-2, with the Class I areas identified.

A key concept in air quality analysis is the definition of “ambient air” as a defined area in which air pollutant effects to air are to be compared to the national and state ambient air quality standards because that area is accessible to the general public (EPA 2019a). For purposes of the SGP, the area outside the area of Operations Boundary is defined as ambient air for modeling analyses is the Operations Area Boundary. This area is illustrated in Figure 3.3-1 and is understood to be the limit of the operations area that would be closed to unrestricted public access. In this area, public access would be prohibited, or restricted through such measures that are accepted as means to control public access (EPA 2019a) such as security checkpoints, physical barriers at points of potential access road and trail entry, and security surveillance patrols.

A May 12, 2021, memorandum developed for the Forest Service by Stantec Consulting Services Inc. (Stantec) outlines the rationale to exclude a portion of the proposed seasonal through-site controlled public access road through the mine operations from the public as approved by both the IDEQ and the accepted by the EPA from ambient air for dispersion modeling purposes (Stantec 2021). This stretch of road is from Stibnite Road (FR 50412) to Thunder Mountain Road (FR 50375). The EPA Region X has indicated that the access road could possibly be excluded from ambient air if sufficient enforceable measures are taken to comply with the 2019 revised policy (EPA 2019a). To comply with this measure, Perpetua has developed an access and transportation management plan that is included as Appendix D in the Air Quality Specialist Report (Forest Service 2022a). The Stantec memorandum provides details that IDEQ, who is responsible for issuing air permits in the state, have excluded the road because of access restriction measures put in place consistent with their rules and requirements in the permit. Lastly, DEQ issued a final Permit to Construct (PTC) on June 17, 2022, that requires an Access Management Plan to be developed outlining specific requirements relating to access control. Further information regarding IDEQ’s ambient air interpretation is available in the PTC, condition 2.7, and the Response to Comments document, Comment 16.

3.3.3 Relevant Laws, Regulations, Policies, and Plans

The Clean Air Act (CAA) of 1970 (42 USC 7401 et seq.), as amended in 1977 and 1990, regulates air emissions and protects air quality and air quality related values across the U.S. Provisions of the CAA that are relevant to the analysis of SGP air quality effects are listed below:

- National Ambient Air Quality Standards (NAAQS)
- Attainment and Non-Attainment Area Designations
- New Source Review Permitting
- New Source Performance Standards (NSPS)
- Mobile Source Regulations
- Visibility and Regional Haze
- GHG Reporting Rule

Certain areas also may be designated for special protection of air quality. All U.S. lands are categorized as either “Class I” or “Class II,” under the CAA, which determines the level of protection from air pollution impacts provided by regulations. Mandatory federal Class I areas include international parks, wilderness areas, and national memorial parks that exceed 5,000 acres, as well as national parks that exceed 6,000 acres, which were in existence prior to August 7, 1977. All other areas were initially classified as Class II. The CAA also gives states and Tribes the ability to request re-designation from Class II to Class I status.

Land and Resource Management Plan: Physical, social, and biological resources on NFS lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. National Forest Land and Resource Management Plans embody the provisions of the NFMA and guide natural resource management activities on NFS land.

In the SGP area, the Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for air quality and include various objectives, guidelines, and standards for this purpose.

National Ambient Air Quality Standards: The EPA, in Title 40 CFR 50, established NAAQS for six criteria pollutants: carbon monoxide (CO), lead, nitrogen dioxide (NO₂), ozone (O₃), particulate matter (PM) including PM less than 10 microns in diameter (PM₁₀) and PM less than 2.5 microns in diameter (PM₂.₅), and sulfur dioxide (SO₂). The NAAQS set two levels of standards for each criteria pollutant: primary standards are health-based atmospheric concentration levels, across specific averaging times, and are protective of public health; secondary standards are in comparable form, and are established to protect commercial and natural resources, and public welfare.

While the EPA sets the NAAQS, most states, including Idaho, are responsible for implementing, attaining and maintaining the standards and this process is done through the State Implementation Plans (SIPs). The IDEQ is the regulatory agency for air pollution control for the State of Idaho. The CAA allows states to adopt their own standards if they are at least as stringent as the NAAQS. The State of Idaho has adopted the NAAQS by reference in IDAPA 58.01.01(107) in lieu of setting its own standards. In addition, Idaho has adopted an ambient air quality standard for fluorides in IDAPA 58.01.01(577). Literature survey and published air pollutant emissions inventory for gold mining do not list fluoride as a
potential emissions concern, and therefore SGP fluoride emissions are considered to be negligible. Table 3.3-1 lists the primary and secondary NAAQS that would apply to the SGP.

μg/m³ = micrograms per cubic meter  CO = Carbon monoxide  m³ = Cubic meters
N/A = Not applicable  NAAQS = National Ambient Air Quality Standards
PM = Particulate matter  NO₂ = Nitrogen dioxide  O₃ = Ozone
SO₂ = Sulfur dioxide  ppb = Parts per billion  ppm = Parts per million

The EPA determines and publishes air quality attainment status in the EPA Green Book (EPA 2021a) based on whether the air quality in the area consistently meets the NAAQS. Areas that persistently do not meet this standard are designated as nonattainment areas. The geographic areas considered in the air quality analysis area are in attainment of the NAAQS for all pollutants and averaging times (IDEQ 2019a).

Federal Air Permitting: The New Source Review process requires facilities to undergo an EPA pre-construction review if they propose building new facilities or modifying existing facilities that would result in a “significant increase” of criteria pollutants per 40 CFR § 52.2376. The New Source Review is further broken down into Major Source Permits for stationary sources that emit criteria pollutants at levels that exceed the defined thresholds for the source type and Minor Source Permits for sources that have emissions below those thresholds. In Idaho, New Source Review air permitting is administered as a State Implementation Plan-approved state program from EPA.

Prevention of Significant Deterioration (PSD) permitting applies to new major sources or major modifications at existing sources for specific pollutants in cases where location of the source is in an
attainment or maintenance area. For these sources, the PSD program requires an assessment of best available control technology and expanded analysis of air quality impacts in Class I areas in 40 CFR 52.21. Areas surrounding the SGP are in attainment with the NAAQS. Applicability of the PSD program to the SGP depends on the magnitude of annual emissions for criteria pollutants.

For new or modified major sources subject to the PSD program, ambient concentrations in Class I and Class II areas also are compared to criteria air pollutant concentration increments that specify the maximum increase of ambient air concentrations of pollutants, or the “consumption of increment”, over the legally established baseline for an area. The analysis of increment consumption in specified areas under the CAA, and the available increment levels are specific to a given location. The allowable increment levels are more stringent in Class I areas, compared to Class II areas. It is the responsibility of the individual states, through their permitting programs, to ensure that the increments are not exceeded due to the development of new or modified facilities. While an increment analysis is required for new or modified major sources, it is recognized that new or modified minor sources also may consume increment. Because the assessment of increment consumption is part of state new source review programs, such an analysis is normally not included in air quality reviews under federal NEPA. However, a simple comparison of modeled pollutant concentrations to the increments for Class I and Class II areas was conducted as part of the SGP air quality analysis. Disclosure of the SGP impacts in comparison to PSD increments helps to inform decision makes and the public regarding the significance of impacts to local air quality.

A Title V operating permit is required for major stationary sources under the Federal Operating Permits Program provided in CAA implementing regulations at 40 CFR 70. Whether a source meets the definition of “major,” depends on the type and amount of air pollutants the source could potentially emit on an annual basis.

A determination was made by the IDEQ that the SGP would not require a Title V permit. This was based on the complete air emissions inventory for stationary sources submitted by Perpetua as part of its application for an air quality permit. On February 18, 2022, Perpetua submitted a PTC application and emission inventory. On June 17, 2022, IDEQ issued a final PTC and Statement of Basis (SOB) stating that the SGP will not require a Title V permit.

Federal New Source Performance Standards: The NSPS are codified at 40 CFR 60 and are incorporated in Idaho air regulations by reference. These rules establish requirements for new, modified, or reconstructed emission units in specific source categories. NSPS requirements include emission limits, monitoring, reporting, and record keeping. Applicable NSPS for the SGP emission sources are:

- 40 CFR 60 Subpart A – General Provisions. Subpart A contains the general requirements applicable to all emission units subject to 40 CFR 60.
- 40 CFR 60 Subpart LL – Standards of performance for metallic mineral processing facilities. All facilities located in underground mines are exempted from the provisions of this subpart. All surface facilities at which construction or modification commenced after August 24, 1982, are subject to this subpart.
• 40 CFR 60 Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. This subpart applies to diesel-fueled reciprocating engines, which would include the compressor and generator engines included in the SGP sources.
• 40 CFR 60 Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants. This subpart applies to the proposed limestone processing plant under the 2021 MMP.

National Emission Standards for Hazardous Air Pollutants: The federal National Emission Standards for HAPs (NESHAP) rules are codified at 40 CFR 61 and 63 and are incorporated in Idaho air regulations by reference. As part of the NESHAPs program, federal maximum achievable control standards are enacted to reduce the emissions of HAPs from both major source and area source categories.

Consideration of NESHAP Subparts in 40 CFR 63 indicates that there are three regulations and general provisions applicable to the SGP’s air emission sources:

• 40 CFR 63 Subpart A – General Provisions. Subpart A contains the general requirements applicable to all emission units subject to 40 CFR 63.
• 40 CFR 63 Subpart EEEEEEE (7E) - NESHAPs for Gold Mine Ore Processing and Production Area Source Category. The rule was promulgated in February 2011, and this NESHAP applies generally to gold ore processing and production of gold-bearing products. This NESHAP is applicable to minor or “area sources” of HAP, and so would apply to the SGP emission sources. Specifically, this NESHAP applies to gold recovery and refining that use carbon processes, non-carbon processes, and mercury retorts. Therefore, the “carbon-in-pulp” process included in the SGP process sequence that adsorbs dissolved gold into the carbon particles is subject to this subpart. The regulation establishes mercury emissions limitations and work practice standards to control mercury emissions from gold production processes.
• 40 CFR 63 Subpart ZZZZZZ – NESHAPs for Stationary Reciprocating Internal Combustion Engines. This subpart applies to the proposed diesel combustion engines at the SGP.
• 40 CFR 63 Subpart CCCCCC – NESHAPs for Source Category: Gasoline Dispensing Facilities. This subpart applies to the proposed gasoline storage tanks at the SGP.

Wilderness Act: The Wilderness Act of 1964 requires that wilderness areas be administered to preserve their wilderness character. The Wilderness Act also created the National Wilderness Preservation System (NWPS) to identify and preserve designated wilderness areas (NWPS 2019a). Further, the Wilderness Act contains specific provisions for managing and protecting these pristine areas (NWPS 2019b). The Forest Service included additional wilderness areas in the air quality screening and modeling for the SGP to evaluate potential impacts on the areas’ natural quality of wilderness character.

Greenhouse Gas Reporting Rule: GHGs are natural or anthropogenic gases that trap heat in the atmosphere and contribute to the greenhouse effect. In October 2009, the EPA issued the Mandatory Reporting of Greenhouse Gas Rule (MRR) in 40 CFR 98, which required reporting of GHG data and other relevant information from large sources and suppliers in the U.S. The gases covered by 40 CFR 98 are CO₂, methane (CH₄), nitrous oxide (N₂O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF₆), and other fluorinated gases. Implementation of the MRR includes the greenhouse gas reporting program applicable to facilities for which actual emissions of GHG are greater than 25,000 metric tons per year. Facilities subject to the MRR are required to submit annual reports to
the EPA (CFR 2016). The Climate Change Specialist Report (Forest Service 2022b) addresses climate change and applicability of the MRR in further detail, but SGP GHG emission estimates would require compliance with the MRR.

**Mobile Source Federal Regulations:** Mobile source air pollution control requirements for gasoline and diesel on-road engines are codified in 40 CFR 80, 40 CFR 85, and 40 CFR 86. These standards are designed to reduce emissions from passenger cars, light trucks, and large passenger vehicles (including sport utility vehicles, minivans, vans, and pickup trucks) and to reduce the sulfur content of diesel and gasoline fuels. Under these provisions, the EPA initially established Tier 1 and Tier 2 emissions standards for the purpose of minimizing emissions from these sources. For the on-road vehicles that would be owned and operated by Perpetua, the regulatory criteria indicate that EPA’s Tier 2 emission standards program would apply.

Provisions for non-road diesel engines are codified in 40 CFR 89, 40 CFR 90, and 40 CFR 1039. Starting in 1996, manufacturers of non-road engines became subject to the EPA’s increasingly stringent Tier 1 through Tier 4 emissions standards, depending on model year and engine size (CFR 2011). All new diesel engines have been required to meet Tier 4 standards since 2015.

EPA’s mobile source regulations in 40 CFR 80 Subpart I Motor Vehicle Diesel Fuel; Non-Road, Locomotive, and Marine Diesel Fuel; and U.S. Emissions Control Area Marine Fuel contain provisions restricting diesel fuel sulfur content for fuel used in mobile sources, in order to prevent damage to the emission control systems. These restrictions would apply to the fuels that would be used by the SGP, as they were phased in for highway diesel fuel starting in 2006 and for non-road diesel fuel in 2007.

**Idaho Minor Source Air Permitting:** The State of Idaho has enacted air quality regulations that are administered by the IDEQ. With respect to new source review permitting, IDEQ uses a PTC program (codified in IDAPA 58.01.01.200-228) that applies to new and modified sources. In this manner, the PTC program serves to protect ambient air quality from impacts due to major and more-numerous non-major stationary emission sources.

The IDEQ requires minor source permits for new facilities that are subject to federal NSPS and/or NESHAP regulations. A determination was made by the State of Idaho that the SGP satisfies the requirements of the PTC program, based on demonstration of the SGP’s potential emissions and controls. This was based on the complete air emissions inventory of stationary sources that was submitted by Perpetua as part of its application to the IDEQ for an air quality permit. IDEQ issued a final PTC (Permit Number P-2019.0047) and SOB for the SGP (Facility 085-00011).

**Idaho Visibility Protection Requirements and Regional Haze Rule:** Atmospheric visibility is defined as the ability of the human eye to distinguish an object from the surrounding background. In 1980, the EPA adopted regulations requiring states to update their State Implementation Plans for protection of visibility in Class I areas in 40 CFR 51 Subpart P (40 CFR 51.300 through 40 CFR 51.307). As a federal land manager of Class I areas, the Forest Service also has affirmative responsibilities to protect air quality and air quality-related values, such as visibility, in the Class I areas.
The federal Regional Haze Rule, adopted by the State of Idaho in IDAPA 58.01.01.665-668, requires states to develop long-term, regional haze, State Implementation Plans for reducing human-caused pollutant emissions that contribute to visibility degradation and to establish goals aimed at improving visibility in Class I areas. Sources of haze-causing pollutants include emissions from industrial sources, tailpipes, agricultural equipment, and practices; and from natural sources such as volcanic emissions, windblown dust, and smoke from wildfires.

According to IDEQ, regional haze in Idaho's natural parks and scenic areas is attributable to a variety of natural and human source of air pollution and is greatly impacted by the effects of climate, such as drought, increased wildfires, and reduced precipitation (IDEQ 2017a).

**Idaho Toxic Air Pollutant Program:** The State of Idaho’s Toxic Air Pollutant Program is a stand-alone risk-based program that regulates approximately 350 pollutants determined by their nature to be toxic to human or animal life or vegetation. The program prohibits emissions of these pollutants in amounts that would injure or unreasonably affect human or animal life or vegetation. Toxic Air Pollutant emissions from industrial sources are compared to screening levels and limited by Acceptable Ambient Concentration for Carcinogens (AACC) (i.e., having the potential to cause cancer) and Acceptable Ambient Concentration (AAC) for non-carcinogenic pollutants. An air impact modeling analysis is required for projects having Toxic Air Pollutant emissions that exceed screening emission levels provided in IDAPA 58.01.01.585 for non-carcinogens, and IDAPA 58.01.01.586 for carcinogens. The modeling analysis must show that the acceptable ambient concentrations for non-carcinogens are not exceeded on a 24-hour average basis, and on a longer-term average for carcinogens. Perpetua submitted an application to IDEQ for review including emissions subject to the Toxic Air Pollutant Program. IDEQ issued a final PTC and SOB for the SGP demonstrating compliance based on the air emissions inventory submitted in Perpetua's application for PTC.

IDAPA 58.01.210.14(a) requires control technologies for toxic pollutants as required to demonstrate compliance with appropriate AAC/AACC values. This is known as Toxic Reasonably Available Control Technology (T-RACT). During the development of the IDEQ permit, specific controls were evaluated and determined to be acceptable and compliant with the standards. As a result, IDEQ is requiring the use of “low-arsenic” quartzite (90 parts per million [ppm] arsenic or less) development rock to be applied for capping haul roads excluding those with the various pits and rock storage facilities. In addition, the drill rigs would include a dust control system with a minimum efficiency of 90 percent. IDEQ issued a final PTC and SOB for the SGP demonstrating compliance with the acceptable ambient concentrations, based on the air emissions inventory submitted in Perpetua's application for the PTC.

**3.3.4 Affected Environment**

The air quality in a given location is characterized by a number of properties that can be physically monitored and evaluated. The existing conditions that may be affected by the SGP include ambient air quality in comparison to the NAAQS, visibility as impacted by regional haze and visible plumes emitted from mine activities, and current rates of atmospheric deposition of mercury, nitrogen, and sulfur compounds. The description of the affected environment addresses these issues and several other parameters that pertain to regional air quality.
3.3.4.1 Criteria Air Pollutants

For SGP-specific baseline concentrations, Perpetua (then Midas Gold) collected 20 months (November 2013 to June 2015) of PM$_{10}$ and PM$_{2.5}$ air concentration data at the approved Stibnite monitoring station (IDEQ 2013). The Stibnite monitor is in the same airshed as the SGP; characterized as mountain valley terrain with little or no industry. Additionally, this SGP particulate monitor is located within the near-field analysis area and was deemed by IDEQ to be representative of background conditions in the locale. The IDEQ formally approved the Monitoring Protocol and Quality Assurance Project Plan in December 2013 (IDEQ 2013). Both the meteorological and air quality monitoring began in November 2013 (Trinity Consultants 2017). After reviewing the data and associated quality control procedures, IDEQ concluded that the calendar year 2014 data for PM$_{10}$ and PM$_{2.5}$ data collected at the Stibnite monitoring station satisfied the applicable regulatory requirements and approved the data as representative for analysis (IDEQ 2015).

For the ambient air NAAQS demonstration, IDEQ identified the source for gaseous pollutant background data as the NW AIRQUEST database for years 2014-2017 (Washington State University 2018) to be used in conjunction with particulate matter data collected at the Stibnite monitoring station. Table 3.3-2 displays these data along with the applicable NAAQS. The areas considered in the analysis of air quality impacts are in attainment of the NAAQS for all pollutants and averaging times (IDEQ 2019a).

4 Average of the 99th-percentile daily maximum 1-hour values for the data collection period.
5 Average of the 99th-percentile daily maximum 1-hour values for the data collection period.
6 Weighted average of quarterly means for the data collection period.
3.3.4.2 Hazardous Air Pollutants

There are no permitted sources of HAP emissions in the vicinity of the SGP area. One source, the Tamarack Mill, LLC. is 75 km away, and reported minor source level emissions of 5.9 tons per year of HAPs in 2014 (Trinity Consultants 2017). Due to absence of permitted HAP emission sources in the air quality analysis area, it can be assumed that baseline ambient concentrations of HAPs are low and less than more industrialized or populated areas.

3.3.4.3 Ozone

For purposes of identifying a baseline value for NAAQS assessment of O₃ impacts due to SGP sources, the IDEQ selected the baseline value from the NW AIRQUEST database for years 2014 through 2017 (Washington State University 2018).

The National Park Service (NPS) has been operating a continuous O₃ monitor at Craters of the Moon National Monument (CRMO) from 1992 to present. This monitor is the only O₃ data source in the region that is not located in an urban area, therefore, it is likely representative of conditions near the SGP and surrounding rural area. The highest one-hour maximum O₃ concentration recorded at the monitor was 91 parts per billion (ppb) recorded in July 1996 and again in August 2008. However, there is no one-hour NAAQS for O₃. The highest O₃ concentration measured at CRMO that is comparable to the 8-hour average NAAQS for O₃, (i.e., annual fourth-highest daily maximum 8-hour average) was 67 ppb which occurred in 2018. The annual trend of the fourth-highest 8-hour average for recent years is shown in Table 3.3-3.

¹ The annual 4th highest 8-hour average averaged over a 3-year period is the NAAQS averaging criteria; these data are annual values, without rolling 3-year averaging.

² These values can be compared to the 2015 8-hour average O₃ NAAQS of 70 ppb.

3.3.4.4 Air Quality Related Values

Air Quality Related Values (AQRVs) are resources sensitive to air quality and include a wide array of resources including, but not limited to, vegetation, soils, water, fish, wildlife, and visibility. Visibility may be affected by impairment due to plume blight or increase in regional haze levels. Plant growth and survival may be adversely affected due to increased ozone concentrations. Deposition of acidic air pollutants may cause episodic or chronic acidification of surface waters and may alter soil chemistry. Elevated deposition of nitrogen or phosphorus can drive species composition changes in both aquatic and terrestrial environments and can change growth and survival rates of plants. Mercury deposition can
impact aquatic and riparian dependent species and can bioaccumulate causing health risks to humans and other species.

The CAA gives federal land managers the affirmative responsibility to protect against degradation of air quality and AQRVs in Class I areas. There are several Class I areas within a 300-km radius of the SGP which were considered for AQRV impact assessments. The nearest Class I areas are Sawtooth Wilderness (SAWT; approximately 80 km south-southeast of the SGP Operations Area Boundary) and Selway-Bitterroot Wilderness (approximately 90 km northeast of the SGP Operations Area Boundary). The Class I areas within a 300-km radius of the SGP Operations Area Boundary are shown in Figure 3.3-2.

The monitoring stations in the far-field analysis area that provide representative background data are listed in Table 3.3-4, and the station locations are mapped in Figure 3.3-3. The Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network stations measure chemical constituents that contribute to regional haze and visibility impairment. The National Trends Network (NTN), operated by the National Atmospheric Deposition Program (NADP) provides data on wet atmospheric deposition. The Clean Air Status and Trends Network (CASTNET), provides information on dry atmospheric deposition, including sulfur and nitrogen compounds, as well as ozone. The Mercury Deposition Network (MDN), also operated by NADP, monitors the atmospheric mercury concentration in wet deposition.

**Visibility**

The CAA sets specific goals for protecting Class I areas from human-caused visibility impacts. Scattering of light by aerosols is the main process that limits visibility in the degrading the clarity and color of what can be seen. Some airborne particles are naturally occurring and include seeds, pollen, spores, fragments of plants and animals, sea salt, dust, and smoke. They also are generated from human-caused sources, which include dust from roads, wind erosion of tilled land, biomass burning, fuel combustion, and industrial processes. In addition, emissions of sulfur, nitrogen, and carbon compounds, which are emitted from industrial sources burning fossil fuels, or from natural sources (e.g., wildfire or dust storms), can be precursors of condensed aerosol particles. In Class I wilderness areas and parks, the Regional Haze Rule requires states to address human-caused sources of air pollution degrading visibility on a regional scale. States use the “impairment” metric to factor out natural sources, such as wildfire smoke, and international contributions outside their control, in tracking their progress in improving visibility in the Class I areas.

One unit used to quantify visibility deterioration is the “visual range,” which is a measurable parameter of atmospheric clarity at a specific monitoring location. A shorter visual range corresponds to more impaired long-range visibility through the atmosphere. Visibility has generally improved in Class I areas across the country, in part due to mandated sulfur restrictions on fuels, and controls on industrial sources of air pollution. Average monthly visual range values in the four Class I areas included in the SGP far-field analysis area are between 223 and 278 km, with significant seasonal fluctuation (Air Sciences 2018a; Federal Land Managers' Air Quality Related Values Work Group 2010).

IMPROVE is a cooperative visibility monitoring effort managed by the EPA, with assistance from multiple U.S. agencies, state agencies, Indian tribes, and associated members in Canada and South Korea. The IMPROVE program measures current and long-term trends in visibility by monitoring, on 3-day
intervals, the pollutants that contribute to reduction in visual range. Historic visibility parameters are presented in Table 3.3-5 for the four IMPROVE stations in Class I areas in the SGP far-field analysis area. The IMPROVE network is designed so that some monitoring sites are used to represent multiple Class I areas in a region.

The visibility data in Table 3.3-5 illustrate how observed impairment can vary seasonally and with local conditions in a given locale. Two different measures of impairment are listed. The “most impaired days” represent the portion of days that exhibit the highest 20 percent of observed visibility impairment and reflects only anthropogenic contributions to haze. Another visibility metric, the “monthly average visual range” includes effects of anthropogenic and natural (e.g., wildfire) contributions to haze, and a higher visual range reflects better clarity. The distribution of most impaired days at the Sawtooth (SAWT1) and Selway-Bitterroot (SULA1) wilderness areas tend to have a greater portion of the most impaired days during the warmer summer months. In contrast, the most impaired days occur more frequently during the winter months at CRMO1 and Hells Canyon Wilderness (HECA1).

Plume visibility is a transient condition that is caused by a source or combination of sources and is the presence of a plume that is visible to an observer some distance from the source.

Assessment of plume visibility is a means to quantify the ability of a viewer to discern a visible plume and is usually evaluated for an observer at the closest point on the boundary of a Class I area of concern. Plume blight occurs when a coherent plume from a source is perceptible against a viewing background (e.g., the sky, or a terrain feature such as a mountain) to a casual observer. The primary parameters of plume blight are the change in visible contrast and color contrast between a plume and background.

**Atmospheric Deposition**

There are two types of atmospheric deposition that can affect AQRVs: 1) wet deposition, which involves the scavenging of particles and gases in the air by clouds and precipitation; and 2) dry deposition, which involves the direct collection of gases and particles in the air by vegetation and solids and liquid surfaces (Wallace and Hobbs 2006). Atmospheric deposition may be due to distant or local sources of pollution.

As described in this section, data for the existing conditions at the monitoring stations nearest to the SGP area indicate that both wet and dry nitrogen deposition either show no clear trend or are trending higher. Nationwide, it has been reported that deposition of oxidized nitrogen species has declined between 2006 and 2016, which may reflect improved nitrogen oxides (NOx) emission control technologies for vehicles and power plants. However, over the same period, deposition rates of reduced forms of nitrogen, such as ammonia, have increased or remained unchanged (NADP 2019). The data presented in this section show that no clear trend is evident in wet or dry sulfur species deposition between 2005 and 2015 at the monitoring sites closest to the SGP area. However, nationwide SO2 emissions have decreased by 76 percent between 2010-2020 (EPA 2022).

CRMO1 = Craters of the Moon National Monument, Monitored Years 2002-17.  
HECA1 = Hells Canyon Wilderness, Monitored Years 2000-17.  
IMPROVE = Interagency Monitoring of Protected Visual Environments.  
Two complementary monitoring networks that collect deposition data are CASTNET and NTN, which collect data related to dry and wet deposition, respectively. Total deposition estimates are provided nationwide by NADP’s Total Deposition Science Committee. They use a hybrid approach combining ambient measurements from CASTNET, NTN, and other air concentration monitoring data with model output to provide gridded estimates of total deposition (NADP 2022; Schwede and Lear 2014). Nearly all CASTNET sites are co-located or are near a corresponding NTN site, which together provide the data needed to track temporal and spatial trends in total deposition.

Deposition of nitrogen and sulfur compounds impact the environment through several pathways. In the atmosphere, \( \text{NO}_x \) reacts with moisture and oxygen to form nitric acid, nitrates, and nitrous oxide, while \( \text{SO}_2 \) reacts to form sulfuric acid, sulfates, and sulfites, which can be transported to the surface by wet deposition. Nitrogen and sulfur compounds formed in the atmosphere are conveyed by dry and wet deposition and can affect soils, water, and biota far from the origination of the precursor emissions. Excessive nitrogen deposition can cause reduction in plant biodiversity and eutrophication (excessive plant and algae growth) in surface waters. This has the effect of reducing the oxygen content of the water, and therefore reduces the population of animal life the water can sustain.

Of somewhat less concern in the Pacific Northwest is acid deposition, which occurs when \( \text{SO}_2, \text{NO}_x, \) and ammonia in the atmosphere react to form sulfuric acid, nitric acid, and ammonium. These compounds can enter surface waters, primarily through wet deposition. These pollutants originate from anthropogenic sources (e.g., burning of fossil fuels in power plants and motor vehicles, and agricultural practices), and to a lesser degree from natural sources (e.g., forest fires and volcanoes).

**National Trends Network**

The NTN provides a nationwide historic record of precipitation chemistry that is reflected in wet deposition rates to soil and surface water. The NTN is part of the NADP that operates several atmospheric monitoring programs. NTN sites are typically located away from urban areas and large point sources of pollution, and many stations are in Class I areas. While stations cannot be established and operated in protected wilderness areas, NTN sites are in many cases located near, or are considered representative of, nearby wilderness area deposition conditions at similar elevations. Each monitoring site measures the quantity of precipitation, and automatically captures samples only during precipitation events. Samples are retrieved from the field on a weekly interval, and analyzed for calcium, magnesium, potassium, sodium, ammonium, nitrate, total nitrogen species, chloride, sulfate, and free acidity (H\(^+\)) (NADP 2022). Wet deposition data is expressed in units of kilograms per hectare per year (kg/ha-yr).

Annual data for three NTN sites closest to the SGP is presented in Tables 3.3-6 through Table 3.3-8. These three sites are located at the CRMO (213 km distant, southeast) Reynolds Creek (264 km distant, south-southwest), and Lost Trail Pass (142 km distant, northeast). Trends in the wet deposition rates of the primary nitrogen and sulfur species (nitrate [\( \text{NO}_3 \)], ammonium [\( \text{NH}_4 \)], and sulfate [\( \text{SO}_4 \)]) are plotted in Figures 3.3-4 through 3.3-6 for the three NTN sites. These trends show the wide variability in annual wet deposition rates in the region, with no clear long-term trend.
Clean Air Status and Trends Network Data

CASTNET is a long-term, dry deposition national monitoring network managed by EPA. The CASTNET sites measure nitrogen and sulfur species, chloride, and base cations (i.e., a positively charged ion) that are used to calculate dry deposition rates. The network was established under the 1990 CAA Amendments to provide accountability for emission reduction programs by reporting trends in pollutant concentrations and acidic deposition (EPA 2018b). Table 3.3-9 shows dry nitrogen compound and dry sulfur compound deposition rates at the two CASTNET monitoring sites closest to the SGP and located in Idaho. These are stations on Nez Perce Tribal Reservation land (82 km distant, north-northwest, and at Reynolds Creek (264 km distant, south-southwest). Like wet deposition, dry deposition is typically expressed in units of kg/ha-yr. Figure 3.3-7 illustrates the trends in annual dry deposition rates at these sites, with dry deposition of sulfur species generally higher than nitrogen species.

Mercury Deposition Network

Inorganic Hg in gaseous and particle-bound forms and mercury oxide can be emitted from mine operations and fossil fuel combustion sources, most notably coal-fired electrical-generating units. Each Hg form has specific physical and chemical properties that determine how far it travels in the atmosphere before depositing to the landscape.

Atmospheric deposition of mercury is of particular concern where the potential exists for contamination of riparian areas and/or surface waters through precipitation and runoff. Although gaseous oxidized Hg and particle-bound Hg deposition are prevalent, all forms of Hg can deposit to local or regional watersheds (Zhang 2009). Once deposited in a body of water, inorganic forms of mercury are converted to a chemical form (methyl mercury) that can become concentrated in fish and can harm the health of individuals who consume these fish, particularly children. In relatively arid regions, such as Idaho, dry Hg deposition may be a larger contributor to atmospheric deposition of mercury compared to wet deposition. National Hg emissions from domestic human-caused sources declined from about 63 tons in 2008 to about 55 tons in 2014, the latest data year available in the EPA National Emissions Inventory (EPA 2017). More than 75 percent of this decline (5.9 tons per year) can be attributed to reductions in Hg emissions from fossil-fueled electric generation plants (EPA 2017).

Annual averages of sampling data are available from the MDN in the region corresponding to the SGP far field analysis area. Three MDN sites have been located at CRMO, Deer Flats (294 km distant, south-southwest), and McCall, Idaho (59.5 km distant, west). The most recent measurements were between 2007 and 2010 and are provided in Table 3.3-10 to serve as an estimate of historical Hg deposition in the region surrounding the SGP area. Total Hg deposition in precipitation (organic + inorganic) is calculated for the MDN in units of micrograms per square meter per year (µg/m2-yr) based on measured mass of Hg deposited over a known sample area (NADP 2018).

1 Individual annual measurements for precipitation and mercury deposition data available for three sites: ID03 Craters of the Moon National Monument; ID98 Deer Flats, Idaho; ID99 McCall Idaho.

2 The three MDN sites within the far field analysis area ceased operation by 2010.

µg/m²-yr = deposition rate as micrograms mercury per square meter per year.

dm = decimeter (1 decimeter = 3.94 inches).

ng/L = nanograms per liter precipitation.

### Mercury Ambient Concentrations

In addition to deposition data, ambient mercury concentrations are measured via the NADP, specifically the Atmospheric Mercury Network (AMNet). AMNet has captured concentration data throughout North America beginning 2006. AMNet has been in 39 sites throughout the years and 12 currently active locations. Each site measures hourly gaseous elemental mercury (GEM) and also measures 2-hr gaseous oxidized mercury (GOM) and particulate bound mercury (PBM2.5). The nearest geographic site to the SGP area is no longer active but was active from December 2008 to August 14, 2017. Table 3.3-11 illustrates the annual average concentrations of each component from December 2008 through November 2015. Only a very limited percentage of data was available from December 2015 through August 2017. For further information and concentrations for other locations please refer to [http://nadp.slh.wisc.edu](http://nadp.slh.wisc.edu).

### Climate and Meteorology

The SGP is located in the central portion of the Salmon River Mountain Range, in central Idaho, approximately 10 air miles east of the village of Yellow Pine. The SGP Operations Area Boundary and the broader analysis area are classified as a Warm-Summer Continental Climate (Weatherbase.com). In this region, the climate typically ranges from warm, dry summers to cold, wet winters. However, the locale of the SGP is semi-arid as a result of the Cascade and Sierra Nevada mountains to the west and the Bitterroot and Rocky Mountains to the north, which effectively prevents large scale intrusion of Pacific moisture.

As described by the Western Regional Climate Center (WRCC), organized storm fronts frequently move through the region during winter, resulting in cold outbreaks, and can produce snowfall over two feet. Cloudy and unsettled weather is common during the winter with measurable precipitation occurring roughly a third of the days. The summer months are typically dominated by high pressure over the Great Basin resulting in warm days with very little precipitation. In general, temperatures in the cooler months average below 30 degrees Fahrenheit (°F) and average above 50°F during the warmer months (WRCC 2018a, 2018b).

Spring months are normally wet and windy with periods of high winds that may persist for days at a time. Weather conditions fluctuate quickly during the spring. Afternoon temperatures in the range of 30 to 50°F with precipitation in the form of rain or snow may occur interspersed with periods of sunny skies and afternoon temperatures between 50 to 70°F. Thunderstorms are not uncommon and are usually accompanied by rain showers and occasional snow. Low elevation snowpack usually melts quickly during the spring, but high elevation snowpack can persist into June or later in the year (WRCC 2018a, 2018b).

The nearest location with a long-term climatological data record is the McCall, Idaho, municipal airport station, which is located approximately 37 air miles west and 1,575 vertical feet below the SGP. The McCall National Weather Service (NWS) station also monitors surface temperature, dew point and wind speed, direction, and highest gust speed (NOAA 2018). While regionally representative, it can be assumed that the McCall airport data would be slightly warmer with lower amounts of precipitation due to its lower elevation compared to the SGP. The average maximum annual temperature is 54°F and during the warmest month (July) the average maximum monthly temperature is 81°F. The average minimum annual temperature is 27°F and during the coldest month (January) the average minimum monthly temperature is 11°F (NOAA 2018). Table 3.3-12 provides the daily average temperature range parameters for the McCall station for the years 1997 to 2008 (WRCC 2018b). The daily average minimum and maximum temperatures for each month recorded in for McCall also are plotted in Figure 3.3-8.

**Figure 3.3-8  Temperature Range Data for McCall, Idaho, and Monthly Precipitation for Big Creek Summit SNOTEL Site**

Figure Source: NRCS 2021; WRCC 2018b
The Big Creek Summit Site is operated by the National Water and Climate Center’s Snow Telemetry (SNOTEL) network. The site is located 28 miles southwest of the SGP at approximately the same elevation and latitude. The site provides data for surface temperature, precipitation, snow water equivalent, and snow depth. The monthly average precipitation and snowfall information for the Big Creek Summit Site can be considered representative of the SGP and is shown in Table 3.3-13 (National Resources Conservation Service [NRCS] 2021). Although the climatological data is quoted for different spans of years, this available data provides covers sufficiently long periods to provide representative average values for historical climate description.

Source: Big Creek Summit Site (NRCS 2021)
1 Data from the Big Creek Summit SNOTEL Station averaged from 1991 to 2020.
2 Data from the Big Creek Summit SNOTEL Station averaged from July 2000 to January 2020.
Avg. = average. In = inches.

Temperature

Between 2010 and 2014, the maximum hourly temperature recorded at the McCall site was 95°F during 2013. Typically, the maximum hourly temperature occurred during July or August. The minimum hourly temperature recorded at the McCall site was -18°F during 2010. In winter, the minimum hourly temperature occurred on numerous days between December and February. Diurnal temperature ranges were the largest in the warmer months (April to September) and decreased during the cooler months (WRCC 2018b). The maximum and minimum daily average temperatures between 1997 and 2008 are shown on Figure 3.3-8.

The hourly temperatures recorded at the Big Creek Summit site would be comparable to the SGP, as this station is at the same elevation. Between 2010 and 2014 highest hourly temperature was 90°F, recorded during 2013. Typically, the maximum hourly temperature occurred during July or August. The minimum hourly temperature recorded at the Big Creek Summit site was -13°F during 2010. Typically, the minimum hourly temperature occurred on numerous days between December and February. Diurnal temperature ranges were the largest in the warmer months (April to September) and decreased during the cooler months (NOAA 2018).

Precipitation

Precipitation data for the Big Creek Summit SNOTEL site over the period 1991 to 2020 show that monthly average totals range from 5 to 8 inches per month during the cool months (November - March)
primarily in the form of snow. The summer is dry, with monthly average precipitation typically less than two inches per month from June through September. Annual precipitation accumulation recorded at the Big Creek Summit site was approximately 51.4 inches in 2010, 47.1 inches in 2011, 54.9 inches in 2012, 35.6 inches in 2013, and 52.8 inches in 2014.

**Wind**

Baseline wind speed and direction data at the Stibnite monitoring station were collected from November 2013 to June 2015. During this period, the strongest winds were from the southwest and from the west-southwest. The mean wind speed was 2.3 meters per second (5.2 miles per hour). Wind directions had a strong tendency from the southwest. Speeds varied widely but tended to be strongest from the southwest. The Stibnite wind distribution data collected at the on-site meteorological station from January 2014 to December 2014 are shown in Figure 3.3-9 (Air Sciences 2018a).

3.4 Climate Change

3.4.1 Introduction

Given that climate change impacts are likely to persist in the region, analysis area resource conditions are expected to be affected. Climate change trends are discussed below by resource. Due to the nature of the resource, climate change is not expected to impact noise, thus this resource is not discussed.

3.4.2 Climate Change Area of Analysis

The climate change analysis area varies depending on the resource affected as described in each resource in this chapter.

3.4.3 Relevant Laws, Regulations, Policies, and Plans

There are currently no federal or state regulatory programs that require GHG emission reductions or controls on new or existing facilities in Idaho. The sections below describe the existing regulatory guidance for GHGs and climate change under the NEPA and from the Forest Service, as well as other guidance from the EPA and state of Idaho for monitoring, reporting, and reducing GHG emissions. Additional descriptions of these guidance documents can be found in the SGP Climate Change Specialist Report (Forest Service 2022b).

Land and Resource Management Plan: There are no specific standards or guidelines related to climate change in the Payette Forest Plan (Forest Service 2003a) or the Boise Forest Plan (Forest Service 2010a). However, Climate Change Considerations in Project Level NEPA Analysis (Forest Service 2009a) provides Forest Service guidance on how to consider climate change in project-level NEPA analysis and documentation. The following basic concepts are outlined in this document:

1. Climate change effects include the effects of agency action on global climate change and the effects of climate change on a proposed project.

2. The agency may propose projects to increase the adaptive capacity of ecosystems it manages, mitigate climate change effects on those ecosystems, or to sequester carbon.

3. It is not currently feasible to quantify the indirect effects of individual or multiple projects on global climate change; therefore, determining significant effects of those projects or project alternatives on global climate change cannot be made at any scale.

4. Some project proposals may present choices based on quantifiable differences in carbon storage and GHG emissions between alternatives.

Mandatory Reporting of Greenhouse Gases Rule: As an initial action under the federal CAA, the EPA established a program in October 2009 for MRR (40 CFR 98). This program requires monitoring and annual reporting of GHG emissions for over 40 source categories if the facility’s annual emissions exceed 25,000 metric tons of GHGs (as CO₂e units). The MRR facilitates collection of emissions data to provide
a basis for future EPA policy decisions and regulatory initiatives. This federal regulation stipulates the methodology for record keeping, emission estimation, and reporting of GHG emissions.

**GHG Major Source Permitting – Tailoring Rule:** In June 2010, EPA issued a final rule (referred to as the Tailoring Rule) setting GHG emission thresholds for CAA preconstruction permits under the PSD and Title V permitting programs (75 Federal Register 31514). The Tailoring Rule established a Title V major source permitting threshold of 100,000 short tons per year for GHGs measured in CO2e. In addition, the Tailoring Rule also imposed the requirement for new major sources of GHG to implement best available control technology to reduce GHG emissions through the new source review process.

In June 2014, the Tailoring Rule provisions regarding GHG major source permitting were remanded by the U.S. Supreme Court (U.S. Supreme Court 2014). The ruling allowed EPA to continue to regulate GHG for sources already subject to regulation as PSD or Title V sources for conventional criteria pollutants.

**2016 Council on Environmental Quality Guidance:** On August 1, 2016, the CEQ issued final guidance describing how federal departments and agencies should consider the effects of GHG emissions and climate change in their NEPA reviews (81 Federal Register 51866). This guidance provided an updated approach to describe climate change impacts (CEQ 2016).

**Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis, EO 13990:** This order was issued on January 20, 2021, to establish a national policy to better promote and protect public health and the environment. Additionally, CEQ will provide a separate notice of its review and potential revisions at a later date. EO 14008 also was issued on February 1, 2021, outlining a government-wide approach toward combating the “climate crisis”. Currently, the 2016 Guidance and other available resources and tools should be employed to assess GHG impacts.

**State and Local Policy:** On May 16, 2007, the Governor of Idaho signed EO 2007-05, Establishing a State Policy Regarding the Role of State Government in Reducing Greenhouse Gases (Idaho Administrative Bulletin 2007). The EO identified two types of actions to be taken: 1) the Director of the IDEQ is to take a lead role in coordinating GHG reduction efforts; and 2) the Director of IDEQ is to develop a state GHG emission inventory and develop recommendations on how to reduce GHG emissions in the state. Table 3.4-1 showing the statewide GHG emissions inventory for Idaho (by sector). GHG emission reduction strategies and/or initiatives have not yet been identified for the state.

### 3.4.4 Affected Environment

Existing conditions for climate change are discussed for the affected resources in terms of baseline GHG emissions in the analysis area, as well as potential effects from climate change on the social, physical, and biological resources in the analysis area. Additional descriptions of these conditions may be found in the SGP Climate Change Specialist Report (Forest Service 2022b).

#### 3.4.4.1 GHG Inventory Information

The GHG compounds of interest are those that would be released due to operation of diesel-fueled and gasoline-fueled engines, and propane combustion for either process needs or heating of buildings.
or release of any hydrofluorocarbons or perfluorocarbons would not be necessary for the SGP. To provide context for emissions associated with the SGP, this section also presents GHG inventory information for national and regional sources.

**National GHG Inventory Data**

Compared to 1990, annual GHG emissions in the U.S. have increased by about 1.79 percent, based on 2019 reported data (EPA 2021b). However, year-to-year emissions are shown to increase or decrease due to changes in the economy, the price of fuel, weather, and other factors.

The EPA reports that 2019 annual total emissions of CO$_2$ were 2.8 percent higher than 1990 totals, while total emissions of CH$_4$ were 15.1 percent lower, and total emissions of N$_2$O were 0.1 percent higher (EPA 2021b). GHG emissions in the U.S. were partly offset by carbon sequestration in managed forests, trees in urban areas, agricultural soils, landfilled yard trimmings, and coastal wetlands. In recent years, there has been a general nationwide trend of declining GHG emissions across most sectors (EPA 2021b).

In 2019, the latest reporting year available, transportation vehicles and electric power generation accounted for 28.6 and 25.1 percent, respectively, of U.S. emissions of GHG. Industrial sources (the reporting category that includes mining activities other than coal accounts for 22.9 percent of GHG emissions nationwide. GHG emissions from industry are mainly associated with burning fossil fuels (e.g., coal, oil, natural gas) for heat energy, as well as emissions from non-road vehicles and equipment, and manufacturing processes to produce goods from raw materials (EPA 2021b).

**GHG Inventory for Idaho**

Table 3.4-1 shows reported statewide GHG emissions within Idaho from 2018. Idaho is a relatively small contributor to U.S. GHG emissions. Based on the total data available from the EPA State Inventory and Project Tool, Idaho produced approximately 31.44 million metric tons (MMT) of CO$_2$e in 2018 (EPA 2021c). These emission estimates are based in large part from representative default values as provided by the EPA. Total national CO$_2$e emissions for 2018 was 5,870 MMT (EPA 2021b). Both yearly estimates include both sources and sinks. Idaho’s total GHG emissions accounted for less than 0.6 percent of U.S. GHG emissions during that period. The Idaho data is broken down into five general categories. These include energy consumption, industrial processes, agriculture, waste (municipal solid waste, wastewater), and land-use and forestry (sinks). Note that the total amount associated with land-use/forestry is a net reduction but included are potential emissions from forest fires. During 2020, approximately 127,214 hectares (314,352 acres) were burned from forest fires (NICC 2021). For the purposes of this analysis, it was assumed that all forest burned was temperate forest such as species like fir and pine.

The three highest contributing sectors to Idaho GHG emissions are energy (19.77 MMT), agriculture (12.64 MMT), and industrial (1.53 MMT). The overwhelming energy contributor is general fossil fuel combustion (primarily industrial and transportation petroleum usage). Mineral mining is not designated separately and is assumed to be a small overall contributor.

Source: EPA 2021c

CO₂ emissions are the vast majority of fuel combustion and industrial processes (~95 percent). Agriculture GHG emissions are primarily comprised of CH₄ (~74 percent). All land use and forestry sinks are calculated as carbon sequestration (CO₂). All solid waste is CH₄ and municipal waste is also mostly CH₄ (~70 percent).

### 3.4.4.2 Climate Change Trends

Climate change is often discussed in terms of plausible futures or scenarios based on precipitation and temperature projections. These scenarios are built on different trajectories of future GHG concentrations, land use, and other factors, due to the uncertainty associated with GHG emissions and concentrations, and uncertainty in climate functions. The Intergovernmental Panel on Climate Change (IPCC) released new emission scenarios in 2013 called Representative Concentration Pathways (RCPs). RCP 8.5 represents a scenario where high emissions continue through 2100 (FHWA 2017); the discussion of emissions and climate change trends throughout this section are based on the projected scenarios under RCP 8.5.
In general, managers are recommended to use the RCP 8.5 scenario for planning and project purposes. This is based on information in the 2018 National Climate Assessment informing that without major reductions in global emissions, it is expected that the temperatures would reach RCP 8.5 levels or even higher temperatures in the future.

The IPCC Sixth Assessment Report documents evidence for the warming of the global climate system since the 1950s, based on observed changes over time periods ranging from decades to millennia (IPCC 2021). In this assessment, the IPCC reports that most land areas have seen a global surface temperature increase of 0.1°C (0.18°F) per decade since 1960, and each of the last three decades has been successively warmer than any preceding decade since 1850. In the Northern Hemisphere, 1983 to 2012 was likely the warmest 30-year period of the last 1,400 years (IPCC 2021).

As described below, the effects of climate change in the analysis area can be seen by review of reported trends in the temperature, precipitation, snowpack, and other indicators of regional climatology. Similarly, statewide climate trends also reflect the measurable effects of regional climate change that will continue to affect the environmental conditions in the analysis area regardless of the alternative implemented. These statewide and regional trends are used as a proxy to discuss current climate trends in the analysis area.

Most of Idaho has seen an increase in average temperatures of 0.56 to 1.1°C (1 to 2°F) over the last century, with the last two decades being the warmest on record (EPA 2016a). Average minimum and maximum temperatures for the middle Rockies region, which includes the Payette, Boise, Salmon-Challis, Sawtooth, and portions of the Caribou-Targhee National Forests, are projected to warm by about 5.6°C (10°F) under RCP 8.5 by 2100, with increases projected to be the largest during summer months (Halofsky et al. 2018). A recent example being the summer 2021 drought throughout much of Idaho. The projected increase in minimum temperature in this region by the year 2100 under the RCP 8.5 scenario will bring the median temperature above freezing, suggesting that a biologically meaningful threshold could be crossed (Halofsky et al. 2018). Additionally, the intensity of heat waves is projected to increase, while cold wave intensity is projected to decrease (Runkle et al. 2017).

Statewide precipitation is highly variable and showed no overall trend in annual average precipitation during the last century. However, the frequency of extreme precipitation events in Idaho has been above average over the past decade. Statewide winter and spring precipitation is expected to increase during the 21st Century, while precipitation in the summer is expected to decrease (Runkle et al. 2017). Overall, precipitation is projected to increase by 5 to 8 percent by the year 2100 under RCP 8.5 (Halofsky et al. 2018). Increased intensity of drought events is expected to occur throughout the 21st Century (Runkle et al. 2017).

Changes in river-related flood risk depends on many factors, but warming is projected to increase flood risk the most in mixed basins (those with both winter rainfall and late spring snowmelt-related runoff peaks) and remain largely unchanged in snow-dominant basins (Mote et al. 2014). Across the northwest region, much of the water supply comes from mountain snowpack, which melts in spring and summer and runs off into rivers, filling reservoirs. As the climate warms, more precipitation falls as rain and less falls as snow and more snow melts during the winter, which decreases the snowpack. Since the 1950s, Idaho’s overall snowpack has been decreasing (EPA 2016a). Lower snowpack and increased drought are likely to
lead to lower base flows, reduced soil moisture, wetland loss, riparian area reduction or loss, and more frequent and possibly severe wildfire. The projected rise in temperatures is expected to increase the average lowest elevation where the snowpack reliably accumulates throughout the winter, which may cause the tree line to shift, as subalpine fir and other high-altitude trees become able to grow at higher elevations. Rising temperatures also could result in earlier melting of the snowpack, further decreasing water availability during the dry summer months (Runkle et al. 2017).

Increasing air temperatures and decreasing summer flows associated with climate change are expected to warm streams by increasing long-wave radiation and warming groundwater inputs (Isaak et al. 2017). Reduced stream cover from changes in woody debris and bank vegetation also can result in increased stream temperatures (Halofsky et al. 2018). A transition from snow to rain, resulting in diminished snowpack and shifts in streamflow to earlier in the season, also could cause reductions in groundwater recharge to aquifers and groundwater discharge to groundwater-dependent ecosystems. Mean annual streamflow projections suggest a slight increase; however, despite these projections, summer low flows are expected to decline.

Climate controls the magnitude, duration, and frequency of weather events (e.g., wind, temperature, relative humidity, and precipitation), which, in turn, drive fire behavior (Halofsky et al. 2018). A warming climate and earlier snowmelt patterns have led to longer fire seasons, and these trends are expected to continue. The size and duration of forest fires, the length of the fire season, and size of areas burned in the West have increased over the past 30 years (Halofsky et al. 2018). The annual area burned, as well as the occurrence of very large wildfires, is projected to continue increasing as temperatures rise and longer fire seasons combine with regionally dry fuels.

3.4.4.3 Geological Resources and Geotechnical Hazards

Current climate change trends, such as increased heavy precipitation events and more precipitation falling as rain instead of snow, could lead to increased soil erosion and change in landcover, which could potentially impact slope stability and avalanche occurrence in the analysis area. Damage due to seismic activity in the area also could be exacerbated by climate-induced instability in the analysis area.

3.4.4.4 Air Quality

Climate-induced changes in weather and seasonality can strongly affect air quality in a specific region. The criteria air pollutants of most concern and potentially most affected by changes in climate, are PM, and ground-level ozone.

PM which primarily consists of sulfate and nitrate compounds, organic carbon, elemental carbon, soil dust, and sea salt. Of most concern to human health are the first four pollutants, because they are typically present as PM$_{2.5}$ and can be inhaled deep into the lungs. Seasonal variation of PM is complex and location dependent; precipitation is the main atmospheric sink for PM (Jacob and Winner 2009). An overall increase in precipitation levels may improve the cleansing of the atmosphere and may increase chemical deposition.
Hotter, drier weather can allow PM and other pollutants to accumulate in the atmosphere or allow emitted PM precursors to persist longer in the atmosphere.

The effect of climate change on PM is complicated and uncertain. As a result of climate change, more frequent and intensified wildfires could become an increasing PM source and decreases in summer precipitation could exacerbate high PM concentrations caused by wildfires (Jacob and Winner 2009).

Wildfires have the potential to cause simultaneous increases of PM$_{2.5}$ and O$_3$ within smoke plumes. (Kalasnikov et al. 2022). Summertime fires allow for more frequent co-occurrence events of the two pollutants, which can be exacerbated by increasing temperatures due to climate change.

The increase in widespread PM$_{2.5}$/ozone co-occurrences during July to September highlights the role of increasingly severe and larger wildfires which contributes to compounding public health hazards throughout the western US.

**3.4.4.5 Soils and Reclamation Cover Materials**

Reduced soil moisture is expected to result from lower snowpack due to higher variation in precipitation and increased annual average temperatures. Higher temperatures may increase the rate at which carbon stored in the soil degrades or is released by fire. More winter precipitation falling as rain instead of snow could generate a higher frequency of runoff and erosional processes from disturbance events, such as fire. Soil erosion by wind and/or water may result in loss of topsoil, which could lead to the degradation of soil quality (Halofsky et al. 2018) and negatively impact reclamation success.

**3.4.4.6 Hazardous Materials**

Although climate change would not impact the likelihood of a spill, it could potentially impact the severity of a spill. Periods of increased precipitation and flooding could have the highest impact on severity of impacts from a release of hazardous materials in proximity to a stream. High stream flows after extreme precipitation events would mean a release into surface waters could travel longer distances before being contained; however, a spill occurring during a seasonal low-flow period would travel a shorter distance, reducing the risk of spill migration.

Although extreme precipitation events occur proportionally less than low-flow periods throughout the year, climate change is expected to increase their frequency.

**3.4.4.7 Surface Water and Groundwater (Quality and Quantity)**

Streamflow, water quality, and water quantity is vital for the survival of numerous aquatic species, as well as for human use. Observations compiled from 21 USGS unregulated stream gauges across Idaho show a decrease in the cumulative water year streamflow by nearly 15 percent over the last half century (University of Idaho 2011). The magnitude of the peak streamflow is expected to increase slightly across the region; however, summer low flows are expected to decline (Halofsky et al. 2018). Additionally, the timing of peak streamflow from 1949 to 2008 has advanced about one week earlier in the spring. Advancement in the timing of peak streamflow is hypothesized to be indicative of changes in the timing of snowmelt and/or phase of precipitation (University of Idaho 2011). Spring and summer streamflow is
expected to continue to decline in basins that have historically relied on snowmelt, and low flow periods are projected to be more prolonged and severe (May et al. 2018). The decline in streamflow is expected to reduce the rate of recharge of water supply in some basins (Halofsky et al. 2018).

Because many biogeochemical processes are temperature-dependent, climate-induced changes in surface and groundwater temperature also could negatively impact the quality of these water resources (Halofsky et al. 2018).

### 3.4.4.8 Vegetation: General Vegetation Communities, Non-native Plants, and Botanical Resources

Gradual changes in the distribution and abundance of dominant plant species and short-term impacts on vegetation structure and age classes are expected as a result of rising temperatures. Increased frequency and duration of drought could impact vegetation ecosystems through changes in soil moisture, which could cause mortality or result in higher species vulnerability to insects and disease. Dominance of nonnative species may be facilitated through more frequent and intense wildfires, causing increased disturbance where native species regenerate more slowly (e.g., sagebrush species). Consequentially, the dominance of nonnative plants could themselves encourage more frequent wildfires and cause changes in the ecology of vegetation assemblages (Halofsky et al. 2018).

Whitebark pine has suffered widespread mortality throughout its range from the combined effects of mountain pine beetle outbreaks and white pine blister-rust infection. Although it is not a dominant species in the area, it is a federally proposed-threatened species and an important tree species to high-elevation ecosystems of western North America (Forest Service 2022g). Fire exclusion amplifies the climate change impacts from insects and disease by allowing succession to shade tolerant species, stressing mature whitebark pines, and limiting opportunities for seedling establishment. Projected warming and drying trends will likely further exacerbate this decline (Fryer 2002).

### 3.4.4.9 Wetlands and Riparian Resources

Changes in groundwater levels in wetlands can reduce groundwater inflow, leading to lower water table levels and altered wetland water balances. These altered water table elevations and streamflow volumes may affect riparian areas and their plant communities by reducing hydrological connectivity between uplands, wetland ecosystems and riparian areas. If water table elevation can be assumed to be in equilibrium with water levels in the stream, reduced base flows could result in lower riparian water table elevations and subsequent drying of streamside areas, particularly in wide valley bottoms. Wetland and riparian plant communities will respond to climate-induced changes in hydrological variables differently as a function of species composition (Halofsky et al. 2018).

### 3.4.4.10 Fish Resources and Habitat

Warmer air temperatures causing decreased snowpack and reduced stream flows can dramatically influence stream temperature and a host of ecosystem processes. Between 1976 and 2015 average August stream temperatures in the western U.S. showed a warming trend of 0.17°C (0.31°F) per decade. These temperatures are predicted to increase an average of 0.72°C (1.3°F) by 2040 and 1.4°C (2.6°F) by 2080.
These warmer water temperatures and lower flows are expected to impact salmon, trout, and other coldwater fish (EPA 2016a). For species dependent upon cold water, such as the federally listed Threatened bull trout, even small rises in temperature can significantly reduce spawning success (Knowles and Gumtow 1996). Additionally, increased wildfire may cause more extensive geomorphic disturbances and debris flows into streams, contributing to more variable environments and declining fluvial connectivity of aquatic habitats (Halofsky et al. 2018). Added to other stressors, such as habitat loss and fragmentation, invasive species, and disease, warmer stream temperatures could impact current spawning and rearing habitat (USFWS 2010).

3.4.4.11 Wildlife and Wildlife Habitat

The region is currently facing unprecedented rates of change in climatic conditions that may outpace the natural adaptive capacities of several native species (Halofsky et al. 2018). Increased climate variability and frequency of extreme conditions will favor species adapted to frequent disturbance, potentially increasing the abundance of invasive species. Impacts to terrestrial species as a result of climate change are already being experienced through habitat loss and fragmentation, physiological sensitivities, alterations in the timing of species life cycles (e.g., seasonal changes impacting migration, hibernation, and reproductive success), and indirect effects (e.g., disruption of species interaction across communities). Most species are expected to exhibit sensitivity to changes in the climate, especially those restricted to high elevations or surface water habitats. Of the special status wildlife species occurring in the analysis area, the flammulated owl (*Otus flammeolus*), wolverine (*Gulo gulo*), and Columbian spotted frog (*Rana luteiventris*) are expected to be the most vulnerable terrestrial populations in the region (Halofsky et al. 2018). Other special status species expected to be impacted include the Canada lynx (*Lynx canadensis*) and Rocky Mountain bighorn sheep (*Ovis canadensis*) (Halofsky et al. 2018).

3.4.4.12 Timber Resources

Forests in the interior Northwest are experiencing rapid change due to increasing wildfires and insect and disease damage, largely attributed to a changing climate (May et al. 2018). Changing climatic conditions are predicted to more than double the area in the Northwest burned by forest fires during an average year by the end of the 21st Century. An increase in wildfires would likely decrease the amount of timber available for harvests and degrade the soil, as well as threaten homes and pollute the air (EPA 2016a). The area of pine forests in the Northwest infested with mountain pine beetles is expected to increase due to climate change over the next few decades, which also could lead to decreased timber harvests (EPA 2016a).

An earlier snowmelt due to warmer temperatures can lead to greater drying of soils and vegetation, creating opportunities for earlier and larger wildfires (Westerling et al. 2006). Combined with other stressors exacerbated by climate, the rate of change in vegetation assemblages may be accelerated, reducing the productivity and carbon storage in most systems.

3.4.4.13 Land Use and Management

Long-term temperature and other climatic changes may potentially affect how lands in the analysis area are used. Climate change may impact recreational use of the land by changing the range and types of
species present through changing habitat conditions (e.g., water quality, temperatures, and streamflow), as well as accessibility for both humans and animal species to various areas through disturbance of roadways or degradation of habitat (e.g., avalanches, flooding, landslides, and wildfires).

3.4.4.14 Access and Transportation

Higher annual average temperatures, extreme weather events such as heavy rainfall and extreme heat, as well as changes in freeze/thaw patterns and snowpack dynamics, can impact roadways and other infrastructure (e.g., bridges and culverts). Roads and other infrastructure that are near or beyond their design life are at the highest risk to damage from flooding, geomorphic disturbances (e.g., landslides), and avalanches (Halofsky et al. 2018).

3.4.4.15 Heritage Resources

Some aspects of climate change may exacerbate natural damage and loss of heritage resources in the analysis area. Increasing wildfires, flooding, melting of snowfields, and erosion can uncover, displace, or destroy artifacts and other cultural or historic resources before they have been identified. Additionally, large disturbances as a result of climate change can alter the condition of vegetation, streams, and other landscape features valued by native populations (Halofsky et al. 2018).

3.4.4.16 Public Health and Safety

Impacts from climate change on public health and safety could be experienced through poor air quality from wildfires, decreased water quality from lower streamflow, more frequent extreme heat events, as well as the hazards associated with flooding or other severe weather from more frequent extreme weather events. While warmer winter temperatures may create safer and more comfortable working conditions.

3.4.4.17 Recreation

Recreational use patterns could be impacted by variable precipitation and rising temperatures, and by the change in conditions that may alter the characteristics and ecological condition of recreation settings. For example, warmer temperatures may affect individual decisions to visit a certain area, and warmer stream temperatures may affect the quantity and quality of aquatic populations for recreational fishing. Higher temperatures and decreased snowpack would affect winter activities dependent on cold temperatures and snowfall, such as skiing and snowmobiling. Other activities may benefit from longer warm and dry seasons (e.g., hiking, camping, mountain biking), but the need for supplemental resources to manage and maintain these recreational areas for a longer period of time may cause personnel and budgetary issues (Halofsky et al. 2018).

3.4.4.18 Scenic Resources

Changing climatic conditions could affect viewers experience of the landscape within the analysis area by wildfires shifting the landscape from homogenous and continuous even-aged timber stands to a mosaic of tree species and structural conditions influenced by fire.
As climate conditions change, vegetation types may experience more mortality from invasive pests, such as beetle kill, and pathogens due to further stress, temperature related or otherwise, which would impact scenery.

### 3.4.4.19 Social and Economic Conditions

Changing climatic conditions could affect the viability of local communities. Communities near the analysis area are rural and rely heavily on tourism and the trade industry to support their economies. The social and economic conditions of the area could be both negatively or positively impacted by climate-induced changes in recreational use (e.g., degraded water quality and low streamflow could decrease recreational use, but increased temperatures could create longer seasons for recreating); however, it is difficult to discern the potential magnitude of these impacts on current socioeconomic conditions. Climate change also could increase the social and economic cost of some public services, such as road repair and transportation infrastructure maintenance, as a result of increased damages caused by extreme weather events; however, the impacts of climate change on infrastructure could add trade employment to the area.

### 3.4.4.20 Environmental Justice

The tribes have specific rights to the affected land in accordance with the Nez Perce Tribe Treaty of 1855, the Fort Bridger Treaty of 1868 (Shoshone-Bannock) and the Shoshone-Paiute Executive Order of 1877. For further details please refer to the Tribal Rights and Interests Special Report (Forest Service 2022q). The tribes also use these lands as a part of their traditional use areas for activities including fishing, hunting, and gathering. The environmental justice communities could be impacted by climate change, as it may exacerbate vulnerability to health threats, economic disadvantages, and social inequity (USGCRP 2016).

### 3.4.4.21 Special Designations

Areas of special designations in the analysis area include wilderness, WSRs, IRAs, and RNAs. Although climate change would not directly impact the designations, it could potentially affect the environmental conditions within these areas. Changes in resource availability and quality, or changes to characteristics in these areas would not necessarily cause a change in designations.

### 3.4.4.22 Payette Forest Carbon Assessment

The Forest Service developed a Forest Carbon Assessment for the PNF in August 2020. The assessment indicated that the carbon storage levels have remained fairly stable with a 1.9 percent increase between 1990-2013. Additionally, negative impacts due to changes in environmental conditions have been limited and offset by forest growth (Forest Service 2020b). Satellite imagery illustrates that fire has been the most prevalent disturbance detected on the PNF since 1990, affecting about 18.2 percent of the PNF, followed by 1.4 percent by insects, 1.2 percent by harvest, and 0.1 percent by abiotic factors (Forest Service 2020b).

Climate and environmental factors, including elevated atmospheric CO₂ and nitrogen deposition, have also influenced carbon accumulation with the PNF. Recent warmer temperatures and precipitation variability may have stressed forests, causing climate to have a negative impact on carbon accumulation
in the 2000s. Conversely, increased atmospheric CO₂ and nitrogen deposition may have enhanced growth rates and helped to counteract ecosystem carbon losses due to historical disturbances, aging, and climate, for some of the forest types located on the PNF (Forest Service 2020b).

Under changing climate and environmental conditions, forests within the PNF may be increasingly vulnerable to a variety of stressors. These potentially negative effects might be balanced somewhat by the positive effects of longer growing season, greater precipitation, and elevated atmospheric CO₂ concentrations. However, it is difficult to judge how these factors and their interactions will affect future carbon dynamics on the PNF, especially with regards to large fire disturbances and increasing insect losses (Forest Service 2020b).

Forested areas on the PNF will be maintained as forest in the foreseeable future, which will allow for a continuation of carbon uptake and storage over the long term. Across the broader region, land conversion for development on private land is a concern and this activity can cause substantial carbon losses (FAOSTAT 2013; Forest Service 2016a). The PNF will continue to have an important role in maintaining the carbon sink, regionally and nationally, for decades to come.

### 3.5 Soils and Reclamation Cover Materials

#### 3.5.1 Introduction

Soils provide support for complex food webs and habitat components, and maintenance of soil quality and analyte concentrations (e.g., metals) is important for soil-hydrologic functions such as water quality, surface water retention, and groundwater recharge (Forest Service 2003a). In addition, soils salvaged prior to construction and mining activities can provide important growth materials that may be used to reclaim disturbed areas.

#### 3.5.2 Soils and Reclamation Cover Materials Area of Analysis

The analysis area for the soils and reclamation cover material resource includes the area where effects may be caused by the proposed activities (FSH.1909.15, 15.2a). The total size of the new and re-disturbed historical disturbance associated SGP is approximately 1,675 acres.

The analysis of existing soils in the effected environment is broken down into two categories, TSRC and DD. The soil analysis area under TSRC utilizes sixth-level HUC at the 12-digit scale (HUC 12) subwatershed boundaries (Figure 3.5-1). This analysis area was selected as it is a reasonable extent to which some of the potential indirect effects of the SGP might extend, such as soil erosion and sedimentation. The TSRC analysis area only includes NFS lands (management of TSRC by the Forest Service does not apply to private lands) within the sub-watersheds in which SGP components would occur. Excluded from the TSRC analysis area are IRAs, RNAs, Wilderness, and private land ownership (including private patented mining claims owned or controlled by Perpetua). HUCs used in this analysis are local subwatershed levels that encompass tributary stream systems. The soil analysis area under DD utilizes the new and upgraded transmission line corridor where activity occurs on NFS lands.
3.5.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to soil and reclamation cover material resources. Additional descriptions of these regulations can be found in the SGP Soils and Reclamation Cover Material Specialist Report (Forest Service 2022c).

**Land and Resource Management Plans:** The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired conditions for wildlife and wildlife habitat and include various objectives, guidelines, and standards related to the success of wildlife habitat in regard to soils.

**36 Code of Federal Regulations 228.8:** Mine operations on NFS lands are required by these regulations to reclaim disturbed surfaces in a timely manner, where practicable, by taking measures to prevent or control on-site and off-site damage to the environment (Requirements for environmental protection: Reclamation, 36 CFR 228.8(g)).

**Forest Service Manual (FSM) 2840:** Reclamation directs that lands disturbed by mining must be returned to a use consistent with long-term forest land and resource management plans. Plans of operations must include specific proposals to reclaim all lands disturbed by mining and address topsoil management (FSM 2840, Section 2841). Measurable performance standards are to be included for all reclamation requirements. A bond or other financial guarantee is normally required to cover the full cost of reclamation. Reclaimed areas may not always achieve the range of desired conditions described in Forest Service management direction.

**Forest Service Manual 2550:** The FSM guidelines on soil management (FSM 2550) require that NFS land be managed to maintain or improve soil quality (Forest Service 2010b). Soil quality is related to the functions that soils perform, including biodiversity, water storage, nutrient cycling, carbon storage, physical stability and support, and filtering and buffering. TSRC and DD generally result in physical, chemical and/or biological changes to soils which impair one or more of these functions. In the context of reclamation, improvement of soil quality and related soil functions should be a primary objective. Practical methods to ensure that reclamation cover materials are suitable are summarized in the guidelines.

**Idaho Administrative Procedure Act 20.03.02:** The IDL regulates surface mining in Idaho. The Mined Land Reclamation Act of 1971 and implementing regulations require that land used for surface mining is reclaimed when mining is completed, meaning the mine operation must return the land to a “productive condition” (IDAPA regulations, Section 20.03.02). The IDL has published a manual of BMPs for Mining in Idaho (1992), which provides techniques and approaches for maintaining water quality and completing reclamation projects. This manual also is referenced in the Payette Forest Plan management direction (Mineral and Geology Resources) as a guide for evaluating the completeness of reclamation plans with respect to mitigating water quality effects.

3.5.4 Affected Environment

3.5.4.1 Soil Landscapes

The analysis area is in the Stibnite Mining District, with prospecting dating back to the late 1800s. Mining began in the 1920s and continued intermittently through 1997. This historical use of the area has resulted in a wide variety of soils modified by human activity throughout the SGP and vicinity, with approximately 522 acres at the SGP considered highly disturbed (Tetra Tech 2017).

Soil at the SGP is generally characterized as weakly developed and coarse textured with a high prevalence of coarse fragments, formed in semi-humid, sub-alpine environments. The dominant parent materials are residual and colluvial material sourced from two main bedrock types: Paleozoic metamorphic rock and younger igneous intrusive rock of the Cretaceous Idaho Batholith. Igneous intrusive rock is much more prevalent in the SGP area. Metasediments (generally quartzite and marble) are primarily found in the vicinity of the West End pit and in lesser amounts near the proposed mill site and southeastern end of the former Yellow Pine open pit. Additional areas of metasediment exposure occur near the proposed mine cap facilities. Bedrock depths are typically deep in alluvial valley bottoms and on side slopes that have a mantle of glacial till, outwash, or colluvium. Very steep, glaciated valley walls typically have bedrock at the surface or at shallow depths. Surface cobbles, stones, and boulders also are locally prevalent, along with bedrock outcrops. While most common on very steep slopes, very stony surfaces also cover approximately 81 acres (5 percent) of the area within the Operations Area Boundary with slopes less than 45 percent (Tetra Tech 2017).

In the analysis area, thin, poorly developed surface and subsurface layers (A, AC and C horizons) have formed on steep slopes (30 to 80 percent gradient) where surface creep is evident by the J-shaped trees. This soil has been interpreted to be generally stable unless it is disturbed or has its vegetative cover removed (Forest Service 1981, 1994). Approximately 366 acres, or 22 percent, of the Operations Area Boundary is considered to have very steep slopes (greater than 45 percent) (Tetra Tech 2020a).

Soil development and thickness of A, AC, and C horizons is strongly correlated with slope position. In general, upper side slopes and ridge tops (runoff or convex positions) experience more erosion and have weaker soil development and shallower soils. Lower side slopes, foot slopes, and toe slopes (concave positions) experience more deposition and have deeper soil development. Mid-slopes or backslopes (transitional areas) experience both erosion and deposition and have intermediate soil development. However, with the exception of the wetland soils located in the SGP survey area, there is little variability in the extent of pedogenesis or thickness of the A and AC horizons (TetraTech 2017 and 2020a). The generalized description of soil development on ridge tops was not assessed by the SGP surveys.
3.5.4.2 Soil Types

Soils in the SGP area are generally young, poorly developed, and often occur on steep slopes. This means their physical and chemical characteristics are often closely associated with the underlying parent materials. Three basic types of parent materials are present and include residuum and colluvium developed in bedrock, alpine glacial till, and alluvium.

The geomorphic setting of the SGP area has resulted in a very complex pattern of soils across the landscape, depending on the presence/absence and depth of the glacial till, colluvium, alluvium, and the composition of the bedrock. The disturbance history also has added another layer of complexity. Pronounced changes in soil properties may occur across short distances. The details of this variability are documented in the Soil Hydrologic Reconnaissance Reports (Forest Service 1974a, 1972, 1969) and the surface soil texture maps developed for the Soil Resources Baseline Study (Midas Gold 2017b).

A map of soil salvage area and depths by soil map unit at the Operation Area Boundary is provided on Figure 3.5-2. Maps of dominant soil types in the mine area and along the proposed new sections of the Burntlog Route are provided in the SGP Soils and Reclamation Cover Materials Specialist Report (Forest Service 2022c). A summary description of mapped soil types and the extent mapped at the SGP is provided in Table 3.5-1 and detailed mapping of the soil map units is available in the SGP Soils and Reclamation Cover Materials Specialist Report (Forest Service 2022c).

Suitable soils are further rated as either good, fair, or poor for reclamation in Table 3.5-2. Sustainable revegetation success depends on the quality of growth media and subjacent material that comprises the vegetation root zone with regard to a number of physical, chemical, and nutrient factors. A root zone analysis based on existing site conditions was utilized to develop suitability criteria for growth media and root zone material (Tetra Tech 2020a) and included characterization of metal concentrations in site soils.

Sustainable revegetation success depends on the quality of growth media and subjacent material that comprises the vegetation root zone with regard to a number of physical, chemical, and nutrient factors. A root zone analysis based on existing site conditions was utilized to develop suitability criteria for growth media and root zone material (Tetra Tech 2020a) and included characterization of metal concentrations in site soils. Suitable soils rated as good generally have loamy soil textures, few coarse fragments, slightly acidic to slightly alkaline pH, and occur on level to gently sloping ground. Unsuitable soils have either very high coarse fragment content; are extremely acidic or very strongly alkaline; or occur on very steep slopes. Soils with a high proportion of surface stones, and soils disturbed by legacy mining activities also are considered unsuitable for reclamation.

Source: AECOM 2020d; Midas Gold 2017b; Tetra Tech 2017, 2019a, 2020a
Suitability Rating based on growth media suitability criteria (TetraTech 2020a) and soil data (TetraTech 2017, 2020a).

**Suitable Soil Types for Reclamation**

Soil map unit number fOD is coarse-silty, mixed, frigid oyaquic dystrocryepts (fOD) formed in alluvium in drainage bottoms near stream channels. This unit is similar to the mOD unit described below but is typically found along the Burntlog Route instead of the mine area. These soils are very deep (>60 inches). This soil has varying mean seasonal temperatures, is saturated but may not be hydric, and typically supports evergreen tree growth in alpine and subalpine communities. Depth to water is between 12 and 24 inches and fluctuates seasonally as indicated by redoximorphic soil features observed in the soil profile. Texture of these soils is silt, loam, silt loam, sandy loam, and loamy sand. Generally, these soils have high organic matter content in the upper soil layers and are suitable as sources for salvage assuming groundwater elevations are reduced. An average depth of 30 inches is available for soil borrow in this map unit.

Soils from map unit fTH are euic, frigid typic haplosaprist (fTH) meaning these soils lack definitive horizons, have elevated pH, and have varying mean seasonal temperatures. This unit is similar to the cTH unit described below but is typically found along the Burntlog Route instead of the mine area. These soil types were observed on side slopes adjacent to the fOD soils. These soils develop by the accumulation and subsequent decomposition of organic matter in forested settings and lack the mineral soil layers and sandy textures found in the fOD soils. These soils are high in organic matter, occur on shallow to
moderate slopes resulting from seeps, and are suitable as salvage material. An average depth of 36 inches is available for soil borrow in this map unit.

Soil pedons described in the sandy-skeletal/loamy-skeletal, mixed typic cryorthents (mTC) are classified as either sandy-skeletal or loamy-skeletal and are derived from slope colluvium or residuum. These soils have a fine loamy texture, typically have above-freezing temperatures, and occur on steep slopes. Soils in this map unit were typically explored to 20 inches or less because of the high percentages of coarse fragments increasing with depth. Geotechnical investigations indicate these soils are very deep with surficial material varying in thickness from a few to over 40 feet (SRK 2012). Thin A horizons transitioning to C horizons are common in this map unit. No evidence of subsurface soil horizon development as required to identify a B horizon was observed. An average depth of 17 inches is available for soil borrow in this map unit.

Soils from map unit sTC are stony typic cryorthents (sTC), formed in colluvium and alluvium which were derived from glacial deposits. These soils are composed of gravels, stones, and cobbles that form on slopes that range from a 10 to 45 percent grade (Tetra Tech 2020a). The soils in this soil map unit (SMU) located within the primary zone of mineralization at the SGP have elevated antimony and arsenic concentrations compared with soils in this same SMU located outside the primary zone of mineralization (Tetra Tech 2021a). A horizons transitioning to AC horizons, then to C horizons are common in this map unit. There are burn areas present in the SMU. An average depth of 12 inches is available for soil borrow in this map unit (Tetra Tech 2020a).

Soils composing the S45+ SMU are typic cryorthents (88 percent of SMU), forming on slopes that are 45 percent and greater. Rock outcrops, predominantly granodiorite with some granite, tend to occur at the higher elevations in this SMU (12 percent of SMU). The soils of this SMU are formed from glacial deposits and weathered granodiorite residuum with a high percent of rock fragments (Tetra Tech 2020a). The soils in this SMU have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a). There are burn areas present in the SMU. Thin A horizons transitioning to AC and C horizons are typical of this SMU. An average depth of 12 inches is available for soil borrow in this map unit (Tetra Tech 2020a).

Soil map unit number mOD is an inceptisol, meaning that the soils form in cold regions and have moderately high silt and clay content. SMU mOD is an oxyaquic dystrochrept that forms near floodplains near stream channels in alluvium. The soils in this SMU run deep, with depth to water being shallow (12 to 24 inches below ground surface). The groundwater likely fluctuates seasonally as expressed by the redoxomorphic features in the soils. The soil characteristics consist of silt to sand textures, generally having a high organic matter content in the upper horizons, until the C horizon is reached, and the soils transition to sand (Tetra Tech 2020a). The soils in this SMU have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a). An average depth of 30 inches is available for soil borrow in this map unit (Tetra Tech 2020a).

Soils from the SMU typic halosparists (cTH), are histosols, meaning that the soils were saturated and heavily composed of organic matter. This is typical of the wetland area which these soils formed. These soils were observed in seeps, toe slopes, and depressions. Standing water was present throughout the SMU, indicating that the water table likely has seasonal fluctuations. These soils occur on shallow-to-
moderate slope faces and tend to lack fluvial depositional patterns, horizonation, and sandy textures. The soils in this SMU are high in calcium, magnesium, potassium, total organic carbon, calcium carbonate, and organic matter in the upper horizons when compared to the other SMUs (Tetra Tech 2020a). The soils in this SMU also have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a). An average depth of 36 inches is available for soil borrow in this map unit (Tetra Tech 2020a).

Areas of previous disturbance (AoD) with GM salvage potential (AoD+) is a map unit that is comprised of land that has been historically disturbed by mining activities, which has since been reclaimed. The majority of the soil remains intact, and the quality and quantity of the soil in this SMU has not been negatively affected by historical mining; therefore, has an average depth of 12 inches of soil that is considered salvageable (Tetra Tech 2020a). The soils in this SMU also have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a).

**Unsuitable Soil Types for Reclamation**

AoDs occur on previous mining activities and include spent heap leach ore storage areas, deposited tailings, development rock dumps, and open pits. These materials are deemed unsuitable for salvage.

Boulder Typic Cryorthents (bTC) is composed of large boulders, talus, and scree material. This SMU occurs on forested areas with burn areas present. These materials are deemed unsuitable for salvage due to the grain size (Tetra Tech 2020a).

The typic cryopsamments (mCP) soil unit consists of rounded gravels, cobbles, and stones. The soils are from fluvial deposits which resulted from the Blowout Creek (i.e., EFMC) dam failure. The slopes of this SMU are less than 10 percent, and soils consist of layered sand deposits, varying in thickness.

The streams SMU are composed of stream beds and stream corridors. This soil unit is dominated by rock fragments and generally is lacking in soil.

The suitability criteria in Table 3.5-2 are applied to the SGP map units in Table 3.5-1.

### 3.5.4.3 Operation Area Boundary

Baseline soil and surface characterization is provided below for the six broad areas of potential disturbance from the Soil Resources Baseline Study (Midas Gold 2017b) that generally correspond to the various SGP areas (i.e., Meadow Creek, Fiddle Creek, Hangar Flats, Yellow Pine, West End, and Infrastructure Areas; see Figure 3.5-2).

**Meadow Creek Area**

This area includes the Meadow Creek valley floor, lower side slopes, and the surrounding valley walls. The Meadow Creek valley floor has deep to very deep, loamy-skeletal, sandy-skeletal, coarse-loamy, and coarse-silty soils developed in alluvium, slope wash, and glacial outwash deposits (map units fOD, mTC). Approximately 54 acres of soils are slightly to strongly acid and have a moderate to high amount of organic matter and generally low levels of essential plant nutrients. Deep alluvial soils cover approximately 32 acres. A seasonal high-water table and soil saturation is present in much of this area.
(Midas Gold 2017b). The glaciated valley walls have weakly developed, loamy-skeletal and sandy-skeletal soils developed in residuum and colluvium derived from weathered granitic bedrock (map units mTc, S45+). Approximately 12 percent of these soils have a high percentage of surface coarse fragments and rock outcrops (sTC) (Midas Gold 2017b; Tetra Tech 2017).

Areas of legacy mining disturbance in the lower Meadow Creek area include the Spent Ore Disposal Area, stream diversions, roads, and vehicle trails. Fifty-six acres, or 10 percent of the area, was mapped as disturbed (AoD) (Tetra Tech 2017). High soil compaction was identified in these areas. Natural disturbance in the Meadow Creek area includes historical wildfires and past landslides and avalanches. Soil disturbance classes identified in burned areas were generally class 0 (none) or 1 (low), and legacy mining disturbance zones were class 2 (moderate) or 3 (severe) (Midas Gold 2017b). Soil disturbance classes are defined in the Forest Soil Disturbance Monitoring Protocol (Forest Service 2009b). Although wildfires are not considered part of the Forest Soil Disturbance Monitoring Protocol, impacts on the soil are recorded.

**Fiddle Creek Area**

The main Fiddle Creek drainage encompasses the lower part of a glacially scoured (cirque) basin and glacial trough walls. The narrow valley floor has coarse-loamy and coarse-silty soils (fOD) developed in alluvium along the stream channel covering approximately 10 acres. The cirque basin and glaciated valley walls have predominantly sandy-skeletal and loamy-skeletal soils (mTC, S45+) developed in colluvium and residuum from granitic bedrock. Rock outcrop and areas of high surface stoniness occur over approximately 5 percent of the area with slopes less than 45 percent. Approximately 4 acres of organic soils (fTH) occur in seepage zones above Fiddle Creek (Midas Gold 2017b).

Four sample locations were investigated in the upper Fiddle Creek area, both receiving laboratory analysis (Tetra Tech 2017, 2021a). Mineral soil textures were found to be predominantly sandy loam and very gravelly loamy sand. The soils are slightly to strongly acid, have a high content of organic matter in the surface (greater than 4 percent), and generally have low to very low levels of essential plant nutrients. Soil saturation was identified in only a few areas in the valley bottom.

Mapped legacy mining disturbance is minimal. One acre was mapped as disturbed (AoD). Former drill roads and drill pads are largely reclaimed. Areas of natural disturbance include both historical wildfires and former landslides and avalanches. Disturbance classes identified in burned areas were class 0 (none) or 1 (low) (Midas Gold 2017b).

**Hangar Flats Area**

This area contains predominantly steep, glaciated side slopes and a portion of the Meadow Creek valley floor. Ninety-six samples were collected in Hangar Flats area, with seven samples receiving laboratory analysis (Midas Gold 2017b; Tetra Tech 2017). The soils are slightly to strongly acidic, have a moderate to high amount of organic matter in the surface, and generally have low to very low levels of essential plant nutrients. The steep glacial trough walls have weakly developed, sandy-skeletal and loamy-skeletal soils (mTC, S45+) developed in residuum and colluvium from granitic bedrock. The valley floor contains large AoDs from drilling and mining activities. Native soils are deep to very deep, coarse-loamy, coarse-
silty, and loamy-skeletal soils developed in alluvium, glacial outwash, and slope wash. Deep alluvial soils (fOD) cover approximately 13 acres. There is a high percentage of histosols (fTH) in seepage zones totaling approximately 23 acres. A seasonal high-water table is present over much of the valley floor and toe-slopes (Midas Gold 2017b).

Areas of legacy mining disturbance include a SODA, Bradley tailings, smelter, mill site, historical creek diversions, private access roads on the hillside, and partially reclaimed zones on the valley floor from past drilling and mining and associated activities. Forty-two acres, or 35 percent of the area, was mapped as disturbed (AoD) (Tetra Tech 2017). High soil compaction was identified in these areas by the Soil Resources Baseline Study. Natural disturbance in the Hangar Flats area includes historical wildfires and past landslides and avalanches. Soil disturbance classes identified in burned areas were generally class 0 (none) or 1 (low), whereas legacy mining disturbance zones were class 2 (moderate) or 3 (severe) (Midas Gold 2017b).

**Yellow Pine Area**

Yellow Pine area contains predominantly steep, dissected mountain slopes on the east side, glaciated valley wall on the west side, and the East Fork SFSR valley floor in between. Soil conditions were investigated at 75 locations in this area, with five samples receiving laboratory analysis (Midas Gold 2017b; Tetra Tech 2017, 2021a). The soils are slightly to moderately acidic, have a moderate amount of organic matter, and generally have low to very low levels of essential plant nutrients. The steep east- and west-facing slopes have weakly developed, loamy-skeletal and sandy-skeletal soils (mTC, S45+) developed in residuum and colluvium from granitic bedrock. The valley floor is mostly disturbed (AoD) by previous mining activities. Undisturbed soils are deep to very deep, loamy-skeletal, sandy-skeletal, and coarse-loamy soils (fOD, mTC) developed in alluvium and slope wash. Deep alluvial soils cover approximately 10 acres. Histosols (fTH) cover approximately 8 acres. A seasonal high-water table is present adjacent to stream courses.

Legacy mining activity in this area is extensive and includes the historic Yellow Pine pit/lake and associated mine benches, waste rock dump, old drill and mine access roads, building sites, and underground portals. Recontouring has occurred in the reclaimed Homestake area (i.e., the northeast portions of the Yellow Pine area). Forty acres, or 20 percent of the area, was mapped as disturbed (AoD) (Tetra Tech 2017). Thirty-six percent of the Yellow Pine area has slopes greater than 45 percent (S45+), a large portion of which also are disturbed. Evidence of wildfire was present in the southwest portion of this area. Disturbance classes identified in burned areas were generally low (Midas Gold 2017b).

**West End Area**

This area is characterized by steep, dissected mountain slopes. Midnight Creek and West End Creek flow through the area and have created sharply incised channels. Much of this area has been disturbed by legacy mine operations (AoD).

Undisturbed soils are predominantly sandy-skeletal and loamy-skeletal (S45+) developed in colluvium and residuum from metasedimentary rocks (predominantly quartzite). Deep alluvial soils (fOD) cover approximately 10 acres. Sixty-one sample locations were recorded in this area, with five samples
receiving laboratory analysis (Midas Gold 2017b; Tetra Tech 2017, 2021a). Surface soil textures in undisturbed areas were predominantly very gravelly loamy sand, loamy sand, sandy loam, and loam. The soils are slightly to strongly acidic, have a moderate to high amount of organic matter, and generally have low to very low levels of essential plant nutrients.

Legacy mining activity in this area is extensive and includes multiple mining pits, haul roads, access roads, waste rock dumps, and areas of deep backfill. Surface materials are bare rock or backfill. Twenty-three acres, or 8 percent of the area, was mapped as disturbed (AoD) (Tetra Tech 2017). Eighty-four percent of the West End area has slopes greater than 45 percent (S45+), a large proportion of which also are disturbed. There was no evidence of wildfire in this area.

**Infrastructure Areas**

These areas are predominantly within the East Fork SFSR valley floor and adjacent fan terraces and lower side slopes. Most of these areas have been previously disturbed (AoD) by mining activities. The SGP facilities that the Infrastructure Areas include: the Crusher ROM Stockpile, Scout Rom Stockpile, Mill, Water Treatment Plant, Water Treatment Plant Laydown, Truck Shop, Main Gate, Main Gate GMS, and the worker housing facility.

One hundred and sixteen (116) sample locations were established in undisturbed soil areas, with 6 samples receiving laboratory analysis (Midas Gold 2017b, Tetra Tech 2021a). Surface soil textures were predominantly fine sandy-loam with a high portion of coarse fragments (sTC) developed in alluvium and colluvium from glacial deposits (Tetra Tech 2020a). Deep alluvial soils cover approximately 6 acres, primarily along haul road routes. Organic soils (fTH) cover approximately 5 acres and were observed in poorly drained areas near seeps and streams with saturation identified in a few (Midas Gold 2017b). The soils are slightly to strongly acidic, have a low to moderate amount of organic matter, and generally have low to very low levels of essential plant nutrients (Midas Gold 2017b).

Areas of existing disturbance include historic town sites, reclaimed haul roads, and mine access and infrastructure areas that show high soil compaction, as well as current roads, parking lots, laydown areas, and camp buildings. Thirty-two acres, or 12 percent of the areas, were mapped as disturbed (AoD) (Tetra Tech 2017). Areas of natural disturbance also exist, caused by both historical wildfires and landslides and avalanches. Disturbance classes identified in burned areas were generally class 1 (low) to class 0 (none), whereas areas disturbed by past mining were class 3 (severe) or class 2 (moderate) (Midas Gold 2017b).

**3.5.4.4 Access Roads**

Geology and geomorphic features of the Burntlog Route were investigated, and the bedrock geology and geomorphology were found to be very similar to those described for the Operations Area Boundary. Granitic bedrock underlies most of the route, with a few inclusions of volcanic and metasedimentary rock (Midas Gold 2017c). The area has been glaciated, creating narrow u-shaped valleys with steep sides and flat valley bottoms. The route is characterized by weakly developed, loamy-skeletal and sandy-skeletal soils (mTC, S45+) developed in residuum and colluvium from granitic bedrock. Deep alluvial soils (fOD) and histosols (fTH) make up approximately 8 percent of the route, occurring in drainageways and slope
seepage zones. It is estimated that 40 percent of the mTC soil map unit would be practically salvageable using heavy equipment (Tetra Tech 2019a).

### 3.5.4.5 Utilities

No soils field investigations occurred for the existing or proposed transmission line ROW. The corridor crosses through 35 different land types on NFS lands. Mapping is available in the Soil Hydrologic Reconnaissance Reports (Forest Service 1969, 1972, 1974a). The Forest Service surveys describe relatively young soils with coarse textures and weak horizon development that are influenced by fluvial cycles. Landform strongly influences soil development as slopes generally have areas of soil loss, equal soil loss-gain, and material accumulation. Deeper soils are located in areas of material accumulation above concave landforms such as swales.

### 3.5.4.6 Off-site Facilities

Locations of off-site facilities include the Landmark or Burntlog Maintenance Facility (depending on which alternative is selected) and the SGLF. The Landmark Maintenance Facility would be constructed on a previously disturbed borrow site. The soils are mapped as mTC ([Table 3.5-1](#)) (Tetra Tech 2017). The Burntlog Maintenance Facility would be located in one of the access roads borrow source locations (4.4 miles east of the junction of Johnson Creek Road and Warm Lake Road along the Burntlog Route). The SGLF would be constructed on an alluvial fan terrace above Big Creek. Soils are mapped as Donnel sandy loam, 2 to 4 percent slopes (NRCS 2017). These are well drained soils formed in alluvium weathered from granite. They have sandy loam textures in the solum, over stratified loamy sand and sandy loam starting below 20 inches. A seasonal water table is greater than 80 inches below the ground surface. Minor inclusions in the map unit include poorly drained soils in the floodplain. The SGLF would be located on private land.

### 3.5.4.7 Soil Contamination/Chemistry

The Operations Area Boundary occurs in an area containing numerous highly mineralized zones, and natural background concentrations of some metals are known to be relatively high in some soils and regolith (i.e., the unconsolidated material below the soil profile and on top of bedrock). In addition, elevated levels of arsenic, antimony, and mercury have been observed in soils contaminated by legacy mine operations (URS 2000a). Some known locations of contamination were previously remediated, but it is possible that additional areas of contamination would be exposed during SGP-related construction, operations, and closure and reclamation. Perpetua evaluated 4,828 exploration soil samples collected from undisturbed areas adjacent to the SGP from 2009 to 2015. The mean concentrations of antimony (14.88 ppm within a range of 0.04 to 2,580 ppm) and mercury (0.972 ppm within a range of 0.005 to 283 ppm) from the samples are high but are still within the highest screening-level phytotoxicity criteria concentrations from various literature references and federal agencies in U.S. and Canada cited in the Reclamation and Closure Plan (Tetra Tech 2021a). The samples were not analyzed using EPA-approved methodologies for environmental analysis. Samples were analyzed using exploration lab methodologies that have more aggressive extraction methods (resulting in potentially higher concentration outputs), which are not typically compared to these environmental screening levels. The mean concentration of arsenic (115 ppm) from the samples is approximately 6.4 times higher than the EPA’s ecological soil
screening level for arsenic (Tetra Tech 2021a). A principal concern regarding the re-use of soil and rock at the SGP is the high metals concentrations that may remain and complicate revegetation plans for reclaimed areas. Total arsenic was identified as having the greatest potential for phytotoxicity in plants growing on reclaimed and legacy mine lands in the Operations Area Boundary.

3.5.4.8 Existing Total Soil Resource Commitment

TSRC is the conversion of a productive site to an essentially non-productive site for a period of more than 50 years. Mining excavations and dumps, roads, dedicated trails, parking lots, and other dedicated facilities (e.g., landfills, borrow sites, surface water management features, etc.) are examples of TSRC. The activity area for TSRC on NFS lands is shown on Figure 3.5-1.

Existing TSRC within the 16 subwatersheds encompassing where disturbance associated with the SGP would occur (Table 3.5-3) was mapped with the use of a geographic information system (ArcGIS) with relevant digital spatial layers including Lidar-generated terrain maps, aerial photographs, road and trail layers, and previous mapping of disturbed areas.

1 The eastern portion of the No Man’s Creek-East Fork SFSR subwatershed is within the PNF and the western portion is in the BNF.
3.5.4.9 Existing Detrimental Disturbance

DD is the alteration of natural soil characteristics that results in immediate or prolonged loss of soil productivity and soil-hydrologic conditions. Areas considered for TSRC are excluded from this requirement, but DD applies to vegetation clearing for new and upgraded utility corridors in areas that are available for multiple uses on NFS lands. The activity area for DD has been defined as the new and upgraded transmission line corridor where it occurs on NFS lands. Existing DD within the transmission line ROW is estimated at 8 percent. This is an estimate based on average extent of DD from ground-based forest harvesting operations in the Forest Service Northern Region (Reeves et al. 2012).

3.6 Noise

3.6.1 Introduction

This section presents a description of the affected noise environment as it relates to humans and human activity. The effects of noise on people can include general annoyance, interference with speech communication, sleep disturbance, and in the extreme, hearing impairment. Effects of noise on non-human species is addressed in Sections 4.12 and 4.13 for fish and wildlife, respectively.

3.6.2 Noise Area of Analysis

The analysis area for noise includes areas within a five-mile radius of the major SGP components (i.e., the Operations Area Boundary, access routes, utilities, and off-site facilities) (Figure 3.6-1). Noise levels vary throughout the analysis area because noise levels attenuate (i.e., decrease) as a function of the distance from the source (i.e., divergence), ground absorption, atmospheric conditions, and the presence of physical barriers.

3.6.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to the Proposed Action and alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to Noise. Additional descriptions of these regulations can be found in the SGP Noise Specialist Report (Forest Service 2022d).

Land and Resource Management Plan: The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for noise and include various objectives, guidelines, and standards for this purpose.
Noise Control Act of 1972: The Noise Control Act of 1972 established a national policy to promote an environment free from noise that jeopardizes public health or welfare and directed the EPA to identify acceptable limits under various conditions that would protect public health and welfare with an adequate margin of safety. EPA published a summary of these acceptable limits in 1978, as follows:

1. $L_{EQ1h}$ of less than or equal to 55 dBA for outdoor areas where people spend limited amounts of time (i.e., school yards or playgrounds).

2. $L_{DN}$ of less than or equal to 55 dBA for outdoor areas at residences, farms, and other areas where people spend varying amounts of time, where quiet is a basis for the use of such areas.

The protective levels should “not be viewed as standards, criteria, regulations, or goals. Rather, they should be viewed as levels below which there is no reason to suspect that the general population will be at risk from any identified effects of noise” (EPA 1978); therefore, the EPA levels are guidance levels rather than enforceable standards or regulations and do not apply to biological resources such as fish and wildlife.

EPA Guidance on Ambient Noise Levels: Guidance on safe noise levels, which can be used to assess impacts of a project on public health and welfare, is available from EPA (1974, 1978). Table 3.6-1 shows outdoor and indoor noise levels identified by EPA to protect public health and welfare, expressed as $L_{EQ24h}$ or $L_{DN}$ (based on the dBA over a 24-hour period). Acceptable noise levels are not “peak” but are 24-hour averages over several years and represent levels where the general population would not be expected to be at risk from the identified effects of the noise (EPA 1978).

</table>

Source: EPA 1978

$\leq$ = less than or equal to

dBA = A-weighted decibel.

$L_{EQ24h}$ = Equivalent sound level for 24-hour period, expressed as dBA.

$L_{DN}$ = Day-night sound level, expressed as dBA.

$L_{DN24h}$ = Day-night sound level, expressed as dBA over a 24-hour period.

29 CFR 1910.95: The OSHA noise standards are described under 29 CFR 1910.95 for sound levels permissible by duration of work per day. When an employee is exposed to noises exceeding the limits, engineering controls and/or personal protective equipment need to be put in place.
30 CFR 62.130: The MSHA noise standards are described under 30 CFR 62.130. A miner cannot be exposed to noise exceeding the permissible exposure level of 115 dBA during any work shift without hearing protection.

3.6.4 Affected Environment

3.6.4.1 Landscape Features

The SGP is located in the PNF in the upper drainage basin for the East Fork SFSR. The area is characterized by narrow valleys surrounded by steep mountains. Elevations along the valley floors range from 6,000 to 6,600 feet above mean sea level. The surrounding mountains and areas in the FCRNRW reach elevations over 9,000 feet above mean sea level. Off-site facilities, much of the Burntlog Route, and the transmission line corridor are in the BNF with a similar topography and terrain. On the western edge of the Operations Area Boundary, access routes and transmission lines are in wider valley bottoms. Tall, dense trees and terrain obstructing the line-of-sight propagation of noise can reduce or eliminate the transmission of noise.

3.6.4.2 Noise-Sensitive Receptors

The SGP is located in the upper East Fork SFSR drainage approximately 44 air miles northeast of the City of Cascade, Idaho. The current access from SH 55 to the SGP is via Warm Lake Road to Johnson Creek Road (in summer) or SFSR Road (in winter), and then the Stibnite Road portion of the McCall-Stibnite Road (Figure 3.6-1).

Within the Operations Area Boundary, the primary human NSRs would be SGP workers. Outside the Operations Area Boundary, the primary human NSRs would be residents and recreational land uses (e.g., campgrounds, lookouts, trails, dispersed recreational uses in wilderness areas, including undeveloped campsites). A total of 12 sites were analyzed for baseline noise conditions and are discussed in the following section. Site 1 represents ambient sound levels near the Operations Area Boundary. Site 4 is not considered an NSR, but the sound levels measured there represent ambient sound levels in adjacent wilderness areas, similar to Site 3. Site 7 also is not considered to be an NSR but characterizes traffic noise along Warm Lake Road.

Residences are located near Warm Lake Road in Cascade and approximately seven miles east of SH 55 on the Southern Pines Plantation Property. Recreational land uses located near Warm Lake Road include the Warm Lake Campground, a Forest Service summer home, and recreational areas along the southwest shoreline of Warm Lake. These noise-sensitive receptors are in the vicinity of both the Johnson Creek Route and the Burntlog Route. Several residences, the Forest Service Camp at Landmark, and the Ice Hole Campground, are located near Johnson Creek Road between Warm Lake Road and Stibnite Road, with additional residences located near Johnson Creek Road in the village of Yellow Pine. The Meadow Creek Lookout is located just north of Meadow Creek Lookout Road, which would be used to access a portion of the Burntlog Route. The FCRNRW is located east of the Burntlog Route and there are several hiking trails in the vicinity, the closest being the Mule Hill Trailhead (NFS Trail [NFST] #219).
### 3.6.4.3 Baseline Ambient Noise Level Measurements

Outdoor baseline ambient sound levels were measured at five locations in the analysis area in July and August of 2014 and at four additional locations in July and August of 2016 (HDR 2017b, 2017c). NSRs analyzed with baseline noise measurements (Sites 1 through 9) are described in Table 3.6-2 and are shown on Figure 3.6-1. Sites with assumed nighttime human use, such as residences and campgrounds, are reported in dBA, L_{DN}; those with assumed daytime-only use are reported in dBA, L_{EQ}.

#### Table 3.6-2 Measured Baseline Ambient Sound Levels

</tr>
</tbody>
</table>
Presented hourly LEQ values (LEQ1h) are averaged from daytime (i.e., from 7:00 AM and 10:00 PM) hourly baseline measurement data collected over a period of multiple consecutive days.

Presented LDN values are calculated from 24-hour baseline measurement data collected over a period of multiple consecutive days (HDR 2017b, 2017c).

The Johnson Creek Route is the current summer access from SH 55 to the SGP via Warm Lake Road, Johnson Creek Road, and Stibnite Road.

The Burntlog Route includes Warm Lake Road, Burnt Log Road, Thunder Mountain Road, and a new connector segment from Burnt Log Road to Thunder Mountain Road.

Three additional locations were identified as human use NSRs but were analyzed without baseline noise measurements (Sites 10 through 12). **Table 3.6-3** provides a description of these NSRs along with reference baseline sound levels. Measured noise levels were not available for these areas, but baseline levels were estimated based on similarity to other sites with measurements.

### 3.7 Hazardous Materials

#### 3.7.1 Introduction

This section addresses hazardous materials other than development rock and process tailings that would be utilized by the SGP. Hazardous materials are substances which may pose a risk to human health, wildlife, or the environment. Hazardous materials that would be used and/or transported for the proposed mining activities include diesel fuel, gasoline, lubricants, antifreeze, process reagents, antimony concentrate, mercury containing residuals, lime, explosives, and other substances.
When not properly managed, hazardous materials can represent potential risks to human health, the environment, and wildlife. Spills or accidental releases of hazardous materials can impact air, surface water, groundwater, soil, vegetation, wildlife, fish and other aquatic resources, and public health and safety; they can occur during transportation to and from a site, during storage and use activities, or through improper disposal of waste materials.

### 3.7.2 Hazardous Materials Area of Analysis

The components of the analysis area for hazardous materials are shown on Figure 2.4-1 and include the Operations Area Boundary (including all operational areas and haul roads); the proposed off-site facilities: SGLF and the Maintenance Facility locations; and the access roads including the Warm Lake Road (CR 10-579), from SH 55 in Cascade past the SGLF, continuing to Landmark; the Burntlog Route: Burnt Log Road (FR 447), new road segments, and segments of Meadow Creek Lookout (FR 51290) and Thunder Mountain (FR 50375) roads; and the Johnson Creek Route: Johnson Creek Road (CR 10-413) and the Stibnite Road portion of the McCall-Stibnite Road (Stibnite Road; CR 50-412), from the village of Yellow Pine to the Operations Area Boundary.

### 3.7.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to the Proposed Action and Alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to Hazardous Materials.

**The Occupational Safety and Health Administration** – Hazard Communication (29 CFR 1910.1200) provides a uniform system of labeling and communicating hazards associated with hazardous chemicals.

**Mine Health and Safety Hazard Communication Standards** – The MSHA regulations specify methods for testing, evaluation, and approval of mining products (30 CFR 5 through 36) and procedures for hazard communication which identifies chemicals at the mine, training to determine hazardous chemicals, and establishes a hazardous communication program (30 CFR 47).

**Idaho Hazardous Waste Regulations** - Idaho enforces regulations on hazardous waste administered through the IDEQ, under Idaho Administrative Code IDAPA 58.01.05. The regulations are identical to federal rules and incorporated by reference where applicable. Large mine operations like the SGP can generate quantities of regulated hazardous waste from laboratory and maintenance activities to require compliance with the federal and state hazardous waste regulations for generation, storage, shipping, and disposal of the hazardous wastes.

**U.S. Department of Transportation (USDOT) Hazardous Materials Transportation Permit** - The permit governs the transport of hazardous materials as defined by the USDOT and requires specific employee training, security, and contingency planning. The USDOT regulations in 49 CFR 100-185 define hazardous materials and establish regulations for the safe and secure transportation of hazardous materials in commerce. Consultation and coordination with the Federal Motor Carrier Safety Administration should be made for shipments of hazardous materials requiring a Hazardous Material Safety Permit, pursuant to 49 CFR 385.403.
Idaho Regulations on Ore Processing by Cyanidation - Idaho Statutes Title 49 Chapter 22 regulates the transportation of hazardous materials and wastes in the state. Regulations include requirements for permits, endorsements, insurance, various enforcement provisions including an enforcement fund, and other provisions to ensure safe hazardous waste transport in the state.

Idaho Regulations on Hazardous Materials/Waste Transport - Idaho has a state regulatory program for Ore Processing By Cyanidation (IDAPA 58.01.13). This program establishes a permitting program for process facilities using cyanide for construction, operations, and closure of facilities that contain, treat, or dispose of process water. The rules specify the necessary contents of a permit application and establish minimum engineering plans and specifications for impoundments, leach pads, and other facilities designed to contain process water.

Department of Justice, Bureau of Alcohol, Tobacco Firearms and Explosives - The agency regulates the sale, possession, transport, storage, security, and use of explosives. The agency also plays a vital role in regulating and educating the explosives industry (27 CFR Part 447).

The International Cyanide Management Code - A voluntary initiative for the gold and silver mining industries and provides guidelines pertaining to the manufacture, transportation, storage, and use of cyanide. Perpetua Resources has indicated their intent to design and operate the cyanidation facility in compliance with the ICMC.

Comprehensive Environmental Response, Compensation, and Liability Act – CERCLA and its regulations enforced by the EPA (Superfund, 40 CFR 300-375) establish liability provisions related to the clean-up of hazardous waste sites, accidents, spills and other releases, pollutants, and contaminants to the environment. Hazardous substances are included in 40 CFR Table 302.4, which lists hazardous substances and reportable quantities in the event of a release of these substances to the environment. In 2021 Perpetua voluntarily entered into an ASAOC with EPA and the Forest Service to conduct certain CERCLA response actions to address environmental effects at the SGP mine site caused by legacy mine operations that preceded Perpetua's involvement in the property (Section 1.3).

Resource Conservation and Recovery Act - Hazardous wastes, as defined in Subtitle C of the federal RCRA regulations, are governed by the EPA in 40 CFR 260-273 and also in the Idaho equivalent state Hazardous Waste Management Act and Idaho Rules and Standards for Hazardous Waste (IDAPA 58.01.05). The regulations apply to the generation, storage, transport, and disposal of regulated hazardous waste. In Idaho, the IDEQ has primacy for regulation of hazardous wastes under IDAPA 58.01.05 which conform to the federal regulatory requirements.

The Oil Pollution Act of 1990 – This act amended the CWA to address prevention, response, and cleanup for oil pollution incidents. This act requires qualifying oil storage facilities to develop SPCC plans in accordance with 40 CFR 112.

EPA Risk Management Plan Rule - Section 112(r) of the 1990 CAA Amendments sets forth a series of requirements aimed at preventing and minimizing the consequences of accidental chemical releases. These requirements are the basis of a rule on “Risk Management Programs for Chemical Accidental Release Prevention” promulgated by the EPA on June 20, 1996 (40 CFR 68). The rule applies to public
and private facilities that manufacture, process, use, store, or otherwise handle regulated substances at or above specified threshold quantities. The rule requires facilities that use extremely hazardous substances to develop a Risk Management Plan with critical information to assist local fire, police, and emergency response personnel in preparation for and response to chemical emergencies.

**National Forest Land and Resource Management Plan** - The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition related to hazardous materials transport, use, and disposal and include various objectives, guidelines, and standards for this purpose.

### 3.7.4 Affected Environment

The SGP area has been extensively disturbed by past mining activities (Figure 3.7-1). Past activities involved the use of hazardous materials including, but not limited to fuels, lubricants, hydraulic oils, and chemical reagents including sodium hypochlorite, sodium hydroxide, copper sulphate, lead acetate, and cyanide (Bradley et al. 1943). See **Section 1.3** for a description of the past mining, milling, and heap leach activities at the site.

#### 3.7.4.1 Operations Area Boundary

Current exploration-related activity is occurring in the three major identified deposits at the mine site: Yellow Pine, West End, and Hangar Flats (Figure 2.4-2) as well as those areas as defined in the Golden Meadows Exploration Project Plan of Operations (Midas Gold 2011, 2016b).

Centrally located support facilities for these exploration activities include the personnel camp, offices, maintenance shop area, a helipad and hangar, and an airstrip.

Perpetua currently stores and uses various substances classified as hazardous materials for ongoing exploration activities. These include petroleum products (e.g., fuels, lubricants, and motor oils), over-the-counter cleaning agents, batteries, tires, and other routine materials used to support drill rigs, generators, water pumps, vehicles, helicopters, and other operating needs (HDR 2017d).

Existing fuel infrastructure for the exploration activities consists of a primary fuel storage area, a secondary fuel storage area, the shop area, and the Hangar Flats fuel storage area. **Table 3.7-1** summarizes petroleum use and storage locations at the existing exploration operations. The primary fuel storage area is covered. The secondary fuel storage area is located near the shop (Figure 3.7-2). The primary diesel generator is located at the personnel camp northwest of the shop area (Figure 3.7-2). The other two generators at the shop area are used as backup power generation for offices and water facilities. Southwest of the shop area is the Hangar Flats fuel storage area.

The storage tanks are situated within secondary containment and routinely checked for tank leakage or spillage. If spills occurred, they would be retained within the secondary containments designed to at least contain 110 percent of the largest tank in the containment. They would be responded to and reported in accordance with the current site SPCC Plan, as well as state and federal regulations (HDR 2017d).
The above ground storage tanks (ASTs) meet the requirements of the Oil Prevention Pollution regulation (40 CFR 112). Perpetua annually reports on-site diesel and Jet A fuel storage in accordance with Tier II reporting requirements under the Emergency Planning and Community Right-to-Know Act (40 CFR 370).

Perpetua has developed a solid waste management plan to assist with the storage, handling, and disposal of solid, special, and hazardous waste streams (HDR 2017d). This plan was developed in accordance with state and federal regulations pertinent to waste, although the existing exploration activities are currently considered a Very Small Quantity Generator under RCRA (40 CFR262.14). The solid waste management plan establishes procedures to identify hazardous waste and provides protocols to track, collect, and dispose of hazardous materials in accordance with state and federal regulations. The plan also outlines methods to minimize the generation of hazardous waste (e.g., using industrial soaps in place of solvents wherever possible).

3.7.4.2 Access Roads

Current access roads used for the transport of hazardous materials to the mine site include Warm Lake Road (CR 10-579) from Cascade, continuing to Landmark and then on Johnson Creek Road (CR 10-413) to the village of Yellow Pine and Stibnite Road (CR 50-412) to the mine site.

The largest volume of hazardous materials currently used at the mine site is petroleum hydrocarbons (e.g., diesel, unleaded gasoline, and Jet A fuel). Fuels are transported to the site via tanker truck; the transportation of these fluids presents the greatest existing risk for spills and releases to the environment. Exploration-related fuel transportation to the site by Perpetua has been occurring since 2011 and, through 2021, has consisted of deliveries by 288 fuel tankers, each with a capacity between 4,000 and 4,500 gallons. This work was performed under the fuel transportation Standard Operating Procedure protocol ESOP_004 Fuel Transportation (Midas Gold 2022). There have been no reported spills or releases associated with the transport of this fuel. There was a small fuel spill associated with a plane crash in February 2012, described further below.

3.7.4.3 Past Releases, Remediation, and Mitigation

Previous reclamation, remediation, and mitigation activities conducted in the SGP area by other operators are described in detail in the Hazardous Materials Baseline Report completed in 2015, updated in 2017 (HDR 2017d). The baseline report also presents a listing of recognized environmental conditions identified during previous environmental assessments conducted in 2010. The January 15, 2021, Action Memorandum by the EPA on the Stibnite Mine Site Time Critical Removal Action, Valley County, Idaho under CERCLA includes information on the mining history, descriptions of past releases of hazardous substances and pollutants, and listing of past remedial actions undertaken at the Stibnite site.

- Past mining activities have deposited metals, spent and neutralized ore, waste rock, and mine tailings over portions of the SGP site. Contaminants associated with past mine operations include metals and cyanide in area soil, groundwater, surface water, seeps, and sediments.
- The Stibnite mine was placed on the Federal Facilities Docket in 1991 CERCLIS No. 9122307607. The Stibnite/Yellow Pine mining area was proposed for listing on the National Priorities List (NPL) by EPA in 2001, but no further action to list the site on the NPL has been pursued by the agency since then.

The legacy mining and processing activities of the SGP vicinity, and the CERCLA status of these disturbances are described in Sections 1.2 and 1.3. Antimony, arsenic, copper, lead, mercury, and cyanide are the hazardous substances and pollutants that have been released into the local environment from mine wastes. Previous mine operations have also caused alterations to local streams and aquatic habitats. Much of the early mining development at the site took place before environmental regulations on the use, handling, and disposal of hazardous materials were in place. While there is no sampling or investigation data to confirm, it is possible that there are spills of hazardous materials (such as petroleum hydrocarbons) located below existing mining wastes at the site.
In January 2021, Perpetua entered into an ASAOC with the EPA and the Forest Service to conduct certain CERCLA response actions to address remaining mine waste impacts and study others (Section 1.3). The first phase of these removal actions is independent of the proposed SGP and are planned to be implemented between 2022 and 2024. Phase 1 removal actions include: diverting clean surface water around certain source areas, Lower Meadow Creek Valley tailings removal (25,000 tons), Bradley Man Camp dumps removal and onsite repository development (200,000 tons), and Northwest Bradley Dump stream waste removal and slope stabilization (100,000 tons). Phase 1 also includes certain baseline studies of conditions at five historic mine adits where mine water is discharging. Following phases would depend on agreement for implementation by Perpetua, EPA, and Forest Service.

The following remediation efforts associated with hazardous substances and other contaminated materials at the mine site have been conducted:

- **1982 to 1997:** mine operators placed the SODA over the previously deposited (and unlined) Bradley mill tailings to reduce erosion of the tailings.
- **1996 to 1997:** mine operator SMI redirected discharge from and draining of the Meadow Creek Pond that lay behind the Bradley Tailings and began construction of a diversion channel to reduce contact of stream flow with the tailings.
- **1998:** Mobil Oil Corporation constructed a new stream channel for Meadow Creek on the south side of the Bradley Tailings and SODA; built a new diversion channel on the north side; lined the old Meadow Creek diversion channel; closed a pond and covered 5 acres of exposed tailings at the upper end of the Bradley Tailings/SODA; regraded and revegetated 100 acres of the Bradley Tailings/SODA; revegetated the diversion channel; and installed stream restoration features (pools and boulders).
- **1998 to 2004:** The EPA, IDL, and IDEQ conducted various tailings and waste removal actions in the Monday Camp area (south end of the Yellow Pine pit); in other areas around the Yellow Pine pit development rock storage areas; and removal and disposal of petroleum contaminated soils in the current shop area.
- **2000:** Waste oil, waste oil-contaminated debris, sludge, and asphalt sealer stored in ASTs at the site were removed and disposed of in accordance with the applicable laws and regulations governing disposal of hazardous waste (HDR 2017d).
- **2002:** The Forest Service removed partial smelter stack and remaining ash in the stack for off-site disposal. Removed contaminated soil and ash from portion of stack that burned in the 2000 forest fire and placed in an unlined Forest Service repository on site, located on top of the NW Bradley Waste Rock Pile. Highly contaminated ash and the wooden stack was disposed off-site at an EPA regulated disposal facility (Clean Harbors).
- **2004 and 2005:** The Forest Service reconstructed about 3,300 feet of Meadow Creek including removal of most of the tailings from the channel on public lands and planting willows. These materials were placed in a containment cell on the SODA. The old channel was partially backfilled and reclaimed.
- **2005:** Removed contaminated and hazardous materials from the Stibnite Mill building and reportedly disposed off-site (HDR 2017d).
- **2009:** The Forest Service regraded and covered a portion of the remaining tailings at the Smelter Flats area including construction of a diversion ditch.
2012: A reportable fuel spill occurred at the site on February 14, 2012. The spill was caused by an airplane crash at the site. The crash released approximately 100 gallons of diesel fuel onto a road adjacent to the airstrip. Snow, ice, and approximately 8 cubic yards of impacted soil were excavated and removed from the site for treatment. No further action was required. Several federal agencies including EPA and the Forest Service, settled its CERCLA liability in the 2012 Bradley consent decree.

Results of a regulatory database search conducted by the Forest Service Krassel Ranger District in 2015 revealed several operators at various sites within the former mine and processing area were listed as having historical incidents or violations involving ASTs and underground storage tanks, RCRA, and CERCLA (HDR 2017d).

- Pioneer Metals installed one gasoline underground storage tank in 1981 near the Stibnite West End Mine in Yellow Pine. It was closed and removed from the ground in 2002.
- Several historical petroleum releases, the largest of which was a major petroleum leak in 1990 from ASTs providing fuel to power generators adjacent to the Pioneer/Stibnite Mine, Inc. processing facilities. Petroleum-contaminated soil was excavated, and limited groundwater remediation was conducted because diesel fuel was reportedly present on the groundwater’s surface. The site of the release was never closed and Stibnite Mine, Inc. was never formally released from liability.
- Several RCRA violations based on earlier mining activities, including a confirmed mining metals release in 1979. RCRA wastes from the Stibnite Mine, Inc. mill building, assay laboratory, pilot plant, and machine shop were containerized and transported off site for proper disposal during historic site cleanup.
- In addition, a recent review of the IDEQ Terradex Facility Mapper, which provides online access to Idaho and EPA regulatory database listings, revealed the following listings associated with former operators of the mine site (IDEQ 2019b): Hecla Mining Company Yellow Pine is listed on Mine Cyanidation Permit Facilities (CN000012), Hecla Mining Company Yellow Pine: General Mine Sites (GM0069); Mine Remediation Action Sites (RA0069); RCRA Hazardous Waste Sites (IDD980665459); and Midas Gold Mine General Mine Sites (GM0301).

### 3.8 Surface Water and Groundwater Quantity

#### 3.8.1 Introduction

The following section describes existing conditions related to surface water quantity, groundwater quantity, and water rights.

#### 3.8.2 Water Quantity Resources Area of Analysis

The analysis area for surface water and groundwater quantity encompasses the land where activities associated with the action alternatives could affect stream flows, groundwater levels, groundwater flow directions, groundwater-dependent ecosystems, and water rights. Such actions would be concentrated at the SGP and include groundwater withdrawal, streambed alteration/diversion, and surface water management. Open pits excavated below the water table require lowering of the water table via removal
of groundwater that would otherwise fill the pit. This is typically achieved by pumping from wells installed around the pit or sumps within the pit. Such pumping can affect nearby surface waters that are to some degree in hydraulic communication with a groundwater system.

The water quantity analysis area encompasses the 12-digit HUCs or sub-watersheds that overlap the proposed SGP. The Operations Area Boundary is near the upper end of the East Fork SFSR within two sub-watersheds: Headwaters East Fork SFSR and Sugar Creek. A portion of the analysis area includes the upper drainage area of the East Fork SFSR (to downstream of the confluence with Sugar Creek), as well as several tributaries of the East Fork SFSR. Those include EFMC (i.e., Blowout Creek), Meadow Creek, Rabbit Creek, Fiddle Creek, Hennessy Creek, Midnight Creek, Garnet Creek, Sugar Creek, and West End Creek, as shown on Figure 3.8-1 (within the “SGP Water Modeling Boundary”). The analysis area for surface water and groundwater quantity that could be directly or indirectly affected by the SGP consists of the area where activities associated with the action alternatives could affect stream flows and/or the quantity of groundwater in storage, groundwater levels, and groundwater transmission.

Groundwater within the analysis area moves primarily through unconsolidated alluvium; groundwater flow via deep bedrock is considered minor in comparison (see discussion of hydraulic conductivity of alluvial materials and bedrock formations presented below). Because most of the groundwater moves through unconsolidated alluvium, the boundaries of the Sugar Creek and Headwaters East Fork SFSR sub-watersheds also represent a reasonable approximation of the area subject to analysis of groundwater quantity impacts arising from the SGP. Note that the SGP might still alter streamflow conditions (including access roads, utilities, and off-site facilities) outside the analysis area; however, such alterations are expected to be minor based on regulatory requirements for these alterations and the application of best management practices.

The analysis area for water rights is the same as used for surface water and groundwater quantity analysis (Figure 3.8-1) and covers the sub-watersheds of Sugar Creek and the Headwaters East Fork SFSR. The Water Rights discussion identifies instream flow water rights held by Idaho Water Resource Board and the Forest Service that are located downstream from the analysis area on the South Fork of the Salmon River and on the Salmon River.

The direct and indirect effects associated with surface water and groundwater quantity are considered in the overall context of the local and regional hydrological and hydrogeological conditions of the affected environment. The following are the main characteristics of those conditions:

- The SGP and surrounding area (i.e., the analysis area) consists of mountainous terrain dissected by typically narrow valleys with steep slopes.
- The hydrology of the analysis area is strongly influenced by seasonal patterns of snow accumulation during the winter, and snowmelt in the spring and early summer.
- Water entering the analysis area as precipitation migrates as surface runoff and shallow groundwater down the mountain slopes and along the valley bottoms in an alluvial aquifer formed by unconsolidated Quaternary deposits of sediment. The alluvial aquifer is documented to be the most groundwater-transmissive formation in the analysis area; it is typically more than 50 feet thick (reaching a thickness of 250 feet at some locations).

• Groundwater in the alluvial aquifer eventually discharges to surface streams. However, at some locations, surface water recharges shallow groundwater during periods of high stream stage.

• Groundwater supports many seep-, spring- and wetland ecosystems referred to as groundwater dependent ecosystems (GDEs).

• A portion of groundwater flow occurs through a network of fractures in shallow bedrock and through fracture zones (encountered in boreholes) and faults. Shallow bedrock is less transmissive than the alluvial aquifer, but more fractured and transmissive than deeper bedrock which is less transmissive.

• The MCFZ acts as an aquitard to bedrock flow based on observations of surface water expressions above the fault zone gouge outcrops and artesian conditions observed in drillholes in its vicinity where it passes between the Yellow Pine pit and West End areas.

• There are four existing water rights held by Perpetua in the vicinity of the Operations Area Boundary that are related to historical mining use, but there are no downstream consumptive-use water rights on the East Fork SFSR.

### 3.8.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the 2021 MMP and action alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to water quality resources. Additional descriptions of these regulations can be found in the SGP Water Quantity Resources Specialist Report (Forest Service 2022e).

**Land and Resource Management Plan:** Physical, social, and biological resources on NFS lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. National Forest Land and Resource Management Plans embody the provisions of the NFMA and guide natural resource management activities on NFS land.

In the SGP area, the Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for surface water and groundwater quantity and include various objectives, guidelines, and standards for this purpose.”

**Federal Laws, Regulations, and Policy:** The USACE regulates the discharge of dredged, and/or fill material within WOTUS pursuant to Section 404 of the CWA. The USACE does not regulate water rights in Idaho, but SGP activities that could alter surface water quantity may be regulated and require a USACE authorization.

In 2004, the Main Salmon, Middle Fork Salmon, Rapid, Selway, Lochsa, and Middle Fork Clearwater rivers were designated as WSRs under the Wild and Scenic Rivers Act (16 USC 1271-1287), which reserves instream water rights for designated rivers, and requires additional administration of existing and new water rights pursuant to state law.

**State and Local Laws, Regulations, and Policy:** The IDWR regulates mine tailings impoundments with dams higher than 30 feet and administers regulations that may have to be considered when a tailings impoundment affects surface water hydrology.
The IDWR also is responsible for administration of water rights, well construction standards, dam safety, and stream channel alteration. Any water right to implement the SGP would need to be granted to the applicant by the State of Idaho through IDWR. The constitution and statutes of the State of Idaho declare all waters of the state to be public but provide the right to divert public waters to put them to beneficial use, which includes mining activities (IDWR 2019; Idaho Const. art. XV, § 1).

A water right is obtained through an application to IDWR. The agency must ensure enough water is available for the water right and that the oldest (senior) water rights are satisfied first (IDWR 2019). Water rights associated with mining projects are protected from forfeiture under Idaho Code 42-223(11).

Valley County reviews development proposals for consistency with the County’s Land Use Development Ordinance. When permits are required by other agencies for all or parts of the application, evidence of the permit and compliance with the provisions of the permit are to be a condition of the land use approval. This includes permits to alter wetlands; permits to construct in flood prone areas; and in other situations where the review and issuance of the permit would ensure that the proposal would be technically feasible.

### 3.8.4 Affected Environment

#### 3.8.4.1 Hydrologic and Geologic Setting

The SGP is located in mountainous terrain with typically narrow valleys and steep slopes. Elevations range from 6,000 to 6,600 feet amsl along valley floors and rise to elevations exceeding 8,500 feet amsl in the surrounding mountains (HydroGeo 2012a).

The climate of the analysis area is influenced by local patterns of wind, precipitation and temperature influenced by topography, slope aspect, and elevation. The analysis area experiences wide annual and diurnal variations in temperature and humidity. During winter, storms typically move through the region resulting in snowfall accumulations of two feet or more. Cloudy and unsettled weather is common during the winter with measurable precipitation occurring on about one-third of the days (Brown and Caldwell 2017a, Section 4; Stantec and Trinity Consultants 2017).

Spring months are normally wet and windy with weather conditions fluctuating quickly. Afternoon temperatures in the 30s and 40s (degrees Fahrenheit) with precipitation in the form of rain or snow may occur interspersed with periods of sunny skies and temperatures in the 50s or 60s °F. Low elevation snowpack usually melts quickly during the spring, but high elevation snowpack can persist into June or later (Stantec and Trinity Consultants 2017).

Although snowmelt may take one month or more in the analysis area, summer weather may begin suddenly with a rapid change to warm and dry weather. Although daytime temperatures are usually warm by June, chilly nights can persist throughout the summer. Showers are common from late spring through summer with an increased frequency surrounding regional high terrain. Afternoon temperatures often rise into the 80s (°F); however, low humidity usually results in overnight temperatures in the 50s (°F) or even cooler (Stantec and Trinity Consultants 2017).

Autumn has cooler weather with daytime highs generally in the 60s (°F) in early fall, dipping into the mid-30s (°F) by mid-November with generally dry conditions, except for the first of the progressive
winter storms. The first cold wave with highs below 20°F and lows around 0°F or lower may arrive any time between late November and late December (Stantec and Trinity Consultants 2017).

The winds in the analysis area follow the traditional up and down valley flow patterns expected in mountain valleys. During the spring months, periods of high winds may persist for days at a time. Winds have a strong tendency toward northeast directionality. Speeds vary widely but tend to be strongest from the southwest (Stantec and Trinity Consultants 2017).

The main East Fork SFSR valley floor is around 6,400 feet in elevation and the tributary valleys—which are at higher elevations like Meadow Creek, Fiddle Creek, Hennessy Creek, and Sugar Creek—all show a strong and pronounced asymmetry with steeper south-facing slopes (Midas Gold 2017e). South-facing slopes are more open to sunlight and warm winds and are thus generally warmer and dryer because of the higher levels of evapotranspiration compared to steep north-facing slopes.

A long-term climatological record is not available for the SGP. Therefore, Parameter-elevation Regressions on Independent Slope Model (PRISM) data compared with the NWS and SNOTEL Secesh Summit site is used to develop average precipitation and temperature estimates (Table 3.8-1). The Secesh Summit site is located 35 miles northwest of the SGP, at a comparable elevation (Brown and Caldwell 2017a).

Source: 800-meter PRISM data, Brown and Caldwell 2017a
The spatial and elevation distribution of average precipitation and temperature are described in more detail in the SGP Water Resources Summary Report (Brown and Caldwell 2017a, Section 4).

The local geology of the analysis area contains four primary lithologic units (Smitherman 1985, USGS 2007, Brown and Caldwell 2017a):

- Neoproterozoic to Ordovician carbonate and siliciclastic metasedimentary rocks,
- Cretaceous Idaho Batholith dioritic to granitic compositions,
- Tertiary dikes, porphyries and volcanics of the Challis Volcanic Field, and
- Quaternary sedimentary alluvium.

Unconsolidated sedimentary deposits appear near the ground surface in the form of alluvial fans, terrace gravels, glacial tills, fluviium, colluvium, and landslide materials. Glacial moraines are evident in the larger valley areas. These unconsolidated alluvial materials are generally confined to the center of valley bottoms, surrounded by bedrock mountain slopes. Precipitation in the area infiltrates and moves through these unconsolidated deposits.

The bedrock in the project area has been compressed into northwest-southeast trending folds and offset with faults of similar trends. The bedrock has also been fractured with lesser amounts of fracturing at depth compared to shallower rock. Groundwater in the area moves through the fractured bedrock under the influence of local gradients and the hydraulic properties of the faults and fractures.

Fault zones were examined for evidence of influence on groundwater flow (HydroGeo 2012a, SPF 2017, Brown and Caldwell 2021e). Evidence of fault influence on groundwater flow was not detected for most faults, except for the MCFZ where artesian conditions on the east side of the fault in the West End pit area indicated that the fault acts as an inhibitor to flow in bedrock. Based on this observation, the MCFZ was represented in the groundwater flow model.

### 3.8.4.2 Surface Waters

#### Streams

The SGP is in the Headwaters East Fork SFSR and Sugar Creek sub-watersheds. The primary surface water features at the SGP include the East Fork SFSR and its tributaries (Figure 3.8-2), as well as intermittent drainages, ephemeral drainages, seeps, springs, wetlands, and ponds.

These features include 10 named surface water channels: the East Fork SFSR, Rabbit Creek, Meadow Creek, EFMC (also known as Blowout Creek), Garnet Creek, Fiddle Creek, Midnight Creek, Hennessy Creek, West End Creek, and Sugar Creek. Most of these streams occur in the Headwaters East Fork SFSR sub-watershed except for Sugar Creek and West End Creek, which are in the Sugar Creek sub-watershed. Brief descriptions of each stream are provided below, and specific drainage and channel characteristics are summarized in Table 3.8-2.

Source: Brown and Caldwell 2017a; HydroGeo, Inc. 2012b

The East Fork SFSR is a perennial stream that flows from southeast to northwest through the SGP and has a drainage basin of 25 square miles upstream of Sugar Creek. It is the principal stream draining the SGP and receives flow either directly or indirectly from all other drainages listed in Table 3.8-2. At ordinary high water, the East Fork SFSR is approximately 2 to 3 feet deep and 25 to 30 feet wide (Brown and Caldwell 2017a).

Historical mining activities have affected the course of the East Fork SFSR in the central portion of the SGP where it flows through a lake that has formed in the Yellow Pine pit. The river enters the pit on the south side and exits from the north. The flow velocity of the East Fork SFSR slows as it passes through the abandoned pit, causing the river to drop much of its sediment load which is then deposited across the lake bottom. The original Yellow Pine pit was excavated to a depth of 125 feet below the current pit lake level, but sediment deposited through time has reduced the lake depth to only 35 feet. The lake has a surface area of approximately 4.75 acres and is estimated to contain approximately 92 acre-feet of water (Brown and Caldwell 2017a). An artificial drop into the pit creates a steep whitewater cascade on the East Fork SFSR where it enters the pit and blocks upstream fish passage above the pit lake.

Meadow Creek originates southwest of the SGP, flows east into the East Fork SFSR, and drains an area of approximately 7.7 square miles. The Meadow Creek headwaters occur in an alpine lake, and the drainage contains multiple wetland complexes. At ordinary high-water, Meadow Creek is approximately 2 to 4 feet deep and 20 to 25 feet wide at the bottom of the drainage (Brown and Caldwell 2017a).

EFMC is a tributary to Meadow Creek that drains an area of 2.4 square miles in the southern end of the SGP (Figure 3.8-2). The creek previously supplied water to a man-made reservoir that provided hydroelectric power and process water to the historical mill and smelter. EFMC is locally referred to as Blowout Creek because the dam forming the reservoir breached in 1965, causing large-scale scouring of the steep channel downstream, and deposition of an alluvial fan. From its headwaters, EFMC meanders...
through a former wetland area that dried up due to stream incision and declining groundwater levels related to the dam failure.

Rabbit Creek and Garnet Creek are small tributaries of the East Fork SFSR that drain 0.6 and 0.5 square miles, respectively. Rabbit Creek is in a steep drainage that has steep side slopes, with numerous seeps and springs occurring throughout its headwaters. Garnet Creek is formed from seeps and springs located in the eastern portion of the SGP. The current shop, camp facilities, and the historical Garnet pit are in the Garnet Creek drainage. Historical waterworks from the 1940s and 1950s as well as a 1990s diversion are present below the former open pit.

Fiddle Creek occurs in a well-defined glacial cirque, drains an area of two square miles, and flows into the East Fork SFSR from the west. The drainage area for Fiddle Creek includes forested and open scree slopes. The middle reach of Fiddle Creek also contains a former reservoir and dam, and a former townsite occurs in the lower reach above and below the County Road. In addition, the creek itself was diverted from its natural outfall site to the north under the County Road through a culvert in the 1980s.

Midnight Creek is a small tributary that drains an area of 0.9 square mile and flows into the East Fork SFSR from the east, just above the Yellow Pine pit lake. Several miles of current and historical exploration and haul roads exist in the Midnight Creek drainage.

Hennessy Creek is a small tributary that drains an area of 0.7 square mile and flows into the East Fork SFSR from the west. The upper end of the drainage is heavily forested, and the lower portion of the drainage has been modified by current access roads and historical mine workings. Hennessy Creek also has a historical water diversion just above the county road that included a large pipe system. The creek flows in the direction of, and then adjacent to, Stibnite Road (CR 50-412) in a channel around the Bradley Northwest mine dump complex, disappears and then reemerges among historical mine development rock piles, and flows through a culvert before entering the East Fork SFSR.

West End Creek flows into Sugar Creek from the south and has a drainage area of 0.6 square mile. The drainage basin of West End Creek was modified extensively and diverted into a now failed French drain system during construction of the large waste rock dump in the middle reach. The current creek flow disappears and reemerges among historical waste rock piles. Several miles of current and historical exploration roads are present in the West End Creek drainage.

Finally, Sugar Creek is a relatively large tributary that drains an area of approximately 17.4 square miles and flows into the East Fork SFSR downstream of the Yellow Pine pit. A portion of the upper Sugar Creek valley has been impacted by past mercury mining activities at the former Cinnabar Mine, located in the upper Cinnabar Creek drainage which is a tributary to Sugar Creek. These activities included underground mine development and operations, development rock disposal, ore processing, deposition of tailings in the valley, construction and use of buildings and housing (several of which still exist), and road construction.

Project Area

Stibnite Gold Project
Stibnite, ID

Data Sources: (Brown & Caldwell 2017)
Nine USGS streamflow gages (Figure 3.8-3) in and near the analysis area provide data to characterize the existing environment. Table 3.8-3 provides streamflow statistics for the nine USGS gaging stations, and Figure 3.8-4 presents average monthly discharge hydrographs for six active USGS gaging stations present in the Analysis Area. The hydrographs illustrate the snowmelt-dominated streamflow pattern observed in the area with flows beginning to rise in March and April and peaking in May or June, before receding to base flow conditions in late summer/fall and remaining low through the winter.

Baseflow and groundwater recharge estimates were derived using data from two of the USGS gaging stations in the analysis area (Brown and Caldwell 2017a). Those two stations, USGS 13311250 (located at the East Fork SFSR above Sugar Creek) and USGS 13311450 (located at Sugar Creek before its discharge to the East Fork SFSR) (Figure 3.8-3), together provide measurements that can be used to estimate groundwater recharge over the entire analysis area by calculating combined baseflow leaving the analysis area. These estimates assume that groundwater flow across the analysis area boundaries are negligible. The estimates also assume that during the periods of low flow (late summer, fall, and winter), the entire flow of each stream is derived from groundwater discharge into the stream. Stream discharges measured at the USGS gages during August, September, and October are interpreted to represent baseflow conditions (Brown and Caldwell 2017a). This interpretation is based on 1) analysis of hydrographs, 2) lack of significant precipitation during these months, and 3) minor flow variations during this period of year.

Considering approximate drainage areas for each of those two stations (18 square miles for Sugar Creek and 25 square miles for the East Fork SFSR [Brown and Caldwell 2017a]), groundwater recharge over the Sugar Creek and East Fork SFSR drainage areas was calculated to 8.1 inches per year over the alluvial valley bottom areas and 6.2 inches per year in the bedrock dominated mountainous areas. These values represent about 20 percent of the estimated annual precipitation for the SGP area, which is equal to 32.19 inches (Brown and Caldwell 2021a).

Figure 3.8-4
Stream Monthly Discharge
Stibnite Gold Project
Stibnite, ID
Data Sources: (Brown & Caldwell 2017)

Average stream flows from 2011-2016
USGS data also were used to derive peak flow statistics for the seven major drainages in the analysis area. Results from the peak flow analysis were summarized in the baseline study (HydroGeo 2012b) and Table 3.8-4. Peak flows were calculated for the bottom of each drainage using the USGS StreamStats program.

cfs = cubic feet per second; peak flow volume statistic reported followed by its 95 percent confidence interval in parentheses

In addition to the USGS data, streamflow data were collected in conjunction with surface water quality baseline sampling on a monthly or quarterly basis at 32 non-USGS monitoring stations (Figure 3.8-5). The monitoring points were selected at upstream and downstream locations to bracket historical and potential future mining activities in the Analysis Area (Brown and Caldwell 2017a). Table 3.8-5 provides streamflow statistics derived from baseline measurements collected between 2012 and early 2016. The mean flows calculated from this dataset for the East Fork SFSR ranged from 4.47 cfs at the farthest upstream monitoring location YP-SR-14, to 31.31 cfs at the most downstream location YP-SR-2. Note
that the baseline monitoring sites are at different locations than the USGS gaging stations, thus providing additional site-specific data proximal to historical and proposed facilities.

Figure 3.8-5
Surface Water Monitoring Locations
Stibnite Gold Project
Stibnite, ID

Data Sources: (Brown & Caldwell 2017)
Seeps and Springs

Seeps and springs are locations where water emanates from the ground to form surface water resources aside from the perennial streams that serve to drain the Analysis Area. Depending on their site-specific conditions, flow from seeps and springs may be perennial or ephemeral and may or may not be enhanced by surface water runoff. Further, depending on site-specific characteristics, seeps and springs may provide an accessible water source for wildlife and vegetation, functioning as the water source for a GDE.

The HydroGeo hydrology field survey completed in 2012 identified 347 hydrologic seep/spring sites within the analysis area (HydroGeo 2012a). The survey identified 37 seeps, 153 seeps with wetlands, 33 springs, 117 springs with wetlands, 1 pond, 2 ponds with wetlands, 3 seep/pond/wetland complexes, and 1 reemerging creek (HydroGeo 2012a). The majority of seeps and springs were found in the glacial cirques that form the headwaters of Meadow Creek, Fiddle Creek, and Hennessy Creek (Figure 3.8-6). Monitoring of seep discharge was established at 23 sites (Figure 3.8-5) during the baseline studies to assess seep and spring contributions and for conceptualization of surficial flow in the analysis area. Mean discharge measured at the sites ranged from 0.0023 cfs at YP-AS-7 in the Meadow Creek drainage to 0.25 cfs at YP-SEBS-2 in the East Fork SFSR drainage. Table 3.8-6 provides statistics for the seep discharge.

HydroGeo (2012a, 2012b) provides the following summary of results of the 2018 spring and seep survey:

- Many of the springs or seeps at higher elevations were located near bedrock outcrops. Due to colluvial cover of the slopes, it was difficult or impossible to recognize whether the water was emanating from a bedrock source, or daylighting as unsaturated flow within the colluvium (e.g., interflow and/or throughflow).

- Springs and seeps were found in the lower Meadow Creek drainage around the spent heap leach ore disposal area.

- Most of the springs were found in alluvial or colluvial slump areas. Emerging water was often found flowing only a short distance above ground before going underground again, especially at higher elevations where snowmelt recharges the colluvial cover.

- Some of the spring and seep sites were located along road cuts. These types of springs and seeps are not naturally occurring and bear no discernible relationship to any local geologic features.

- The results of the survey indicate no clear-cut relationship between the springs and seeps and mapped geologic structures and stratigraphy.

Waters of the United States

WOTUS are defined by 33 CFR 328.3 as: all waters that are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters that are subject to the ebb and flow of the tide; all interstate waters including interstate wetlands; all other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation or destruction of which could affect interstate or foreign commerce including any such waters that are or could be used by interstate or foreign travelers for recreational or other purposes, or from which fish or shellfish are or could be taken and sold in interstate or foreign commerce, or that are used or could be used for industrial purpose by industries in interstate commerce; all impoundments of waters otherwise defined as Waters of the U.S. under the definition; tributaries of waters identified in paragraphs (a)(1)-(4) of this section; the territorial seas; and wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (1)-(6) of this section. Various related definitions, Supreme Court findings, and regulatory guidance currently affect how the definition is applied. In part, the CWA, through Part 404, requires permits before fill can be placed in jurisdictional WOTUS. WOTUS are regulated by the USACE. This section discusses non-wetland WOTUS; wetland WOTUS are described in Section 3.11.

Surface Water Rights

Within the Analysis Area, there are no federal, state, or other private surface water rights aside from two water rights held by Perpetua (Table 3.8-7). However, the Idaho Water Resource Board and the Forest Service hold minimum flow water rights downstream of the SGP on the East Fork SFSR, SFSR, and the main stem of the Salmon River.

Source: Midas Gold 2016a (Table 8-1)
cfs = cubic feet per second.

These water rights at the SGP are specific to historical use related to activities in the 1980s and 1990s. While these are valid water rights, the specific points of diversion, place of use, and beneficial use does not reflect planned SGP activities and would need to be adjusted through the transfer process, and through filing additional applications for permit. It is not necessary to record a water right for the random diversion of water for fire suppression purposes. However, water used for dust control and exploration activities requires a water right.
A review of IDWR water right records indicates that there are no downstream consumptive-use water rights on the East Fork SFSR until after the river merges with Johnson Creek (HDR 2017e). The Idaho Water Resource Board maintains minimum streamflow rights on various rivers and creeks in the state, including a location near the end of the East Fork SFSR below the confluence with Johnson Creek, which is covered under water right 77-14190. A minimum streamflow is the amount of flow necessary to preserve stream values, including protecting fish and wildlife habitat, aquatic life, navigation, transportation, recreation, water quality, or aesthetic beauty. The minimum flow varies throughout the calendar year (Table 3.8-8), with a base flow minimum of 173 cfs between October 1 and October 31 as measured on the East Fork SFSR at the confluence of the East Fork SFSR with the SFSR. Water Right 77-14190 is subordinate to future non-domestic, commercial, municipal, and industrial uses and future non-domestic, commercial, municipal, and industrial development up to 8.2 cfs.

Source: HDR 2017e  
cfs = cubic feet per second.

Idaho Water Resource Board also holds a minimum streamflow water right downstream (approximately 26.4 miles from the SGP and approximately nine miles from the East Fork SFSR confluence) on the South Fork of the Salmon River (77-14174). Water Right 77-14174 is also subordinate to all future domestic, commercial, municipal, and industrial uses and future non-domestic, commercial, municipal, and industrial development up to 20.6 cfs.

The Forest Service holds two water rights on the Salmon River (75-13316 and 77-11941) below the Shoup quantification site (Shoup gage) which is upstream of the South Fork confluence. These are instream, non-consumptive water rights that maintain flows for the WSR designated segment of the Salmon River. When flows measured at the Shoup gauge are less than 13,600 cfs, the minimum in-stream flow rates provided by the water rights range from 1,200 cfs for the period of September 1 to September 15 to 9,450 cfs for the period of June 1 to June 15. The SFSR joins this segment of the main stem Salmon
River approximately 64.6 miles downstream from the SGP area. These water rights are subordinated to all water rights claims filed in the Snake River Basin Adjudication as of the effective date (September 1, 2003) of the Stipulation among the U.S., the State of Idaho, and other objectors. They also are subordinated to specified quantities of future beneficial use rights. Additional detailed information regarding these two water rights can be found in Water Right Reports (referenced by water right number) available on the IDWR website (https://idwr.idaho.gov/water-rights/).

**Surface Water Diversion and Discharge**

Under current conditions, surface water diversion within the Analysis Area is limited to water usage by Perpetua in accordance with its current surface water rights. As part of the proposed mining activity, additional surface water diversion from the East Fork SFSR is proposed from a location upstream of the proposed fish tunnel (Brown and Caldwell 2021b). New appropriation can be accommodated under the subordination amounts specified in the Idaho Water Resource Board and Forest Service minimum flow rights for future beneficial use and are most relevant to the SGP.

Storage of water is not subordinated as specified in the partial decree for the two Federal Wild and Scenic rights (Fifth Judicial District 2004) which states that “[t]hese subordinated amounts do not include storage, other than incidental storage, which is defined as storage not more than a 24-hour water supply for any beneficial use.”

There are currently no permitted wastewater discharges to surface water within the analysis area. Stormwater runoff associated with current exploration activities has been covered under the March 2021 MSGP administered by IDEQ. The 2021 MMP activity includes a treated industrial wastewater discharge and a treated residential wastewater discharge that would be permitted under the State of Idaho’s IPDES process. A discharge to Meadow Creek would be located adjacent to the TSF Buttress and discharges to East Fork SFSR would be located west of the Stibnite Worker Housing Facility and west of the Process Plant (Brown and Caldwell 2021b).

### 3.8.4.3 Groundwater

Groundwater flow in the analysis area occurs primarily in the Quaternary unconsolidated deposits in the valleys (composed of alluvium, glacial, and glaciofluvial materials), and through the unconsolidated deposits covering the mountainsides (e.g., glacial moraines, talus, colluvial, and landslide materials). The unconsolidated Quaternary deposits in the valleys form what is referred to as an alluvial aquifer. Some groundwater flow also occurs within bedrock in areas where secondary porosity including fractures and fracture zones are present and sufficiently connected to promote water flow (SPF 2017). In select locations, historical mine workings, such as adits, that penetrate the bedrock units act to promote groundwater flow in bedrock.

The unconsolidated deposits receive water from snowmelt, precipitation, and infiltration of surface runoff from upland areas, and groundwater discharge from the underlying bedrock. Groundwater discharges primarily to streams, but also supports wetlands, seeps, and springs. The water discharging from unconsolidated deposits to the surface via seeps and springs often flows only a short distance over the surface before infiltrating back into the unconsolidated materials (SPF 2017).
Groundwater Observations

Baseline characterization of groundwater, including water levels, gradients, and flow directions is based on measurements collected from 65 groundwater wells and four exploration boreholes converted to vibrating wire piezometers (Brown & Caldwell 2017). Of those 65 wells, 49 are completed in alluvium, and 16 in bedrock. Well locations are provided in Figure 3.8-7 with well completion information summarized in Table 3.8-9. Groundwater level data used for baseline characterization was collected from December 2011 through December 2019 (SPF 2017, Brown and Caldwell 2021f). Collection of groundwater level data is ongoing.

Spatially, alluvial monitoring wells characterize alluvium where it is present, primarily in the valley bottom areas (Figure 3.8-7). Bedrock monitoring wells are also located primarily in valley bottom areas where they can observe the effects of interactions between the lower flow bedrock lithologies and the higher flow alluvium (Figure 3.8-7). Most bedrock wells in the analysis area are screened within the batholith unit, with wells in the northeastern part of the project screened within the metasedimentary units (Figures 3.8-8 and 3.8-9). Tertiary intrusive rock units are interspersed within the other bedrock lithologies and are generally not specifically targeted by monitoring well completions due to their generally low permeability and small volumetric presence compared to the batholith and metasedimentary units.

Most wells and boreholes (completed in alluvium or bedrock) exhibit seasonal groundwater level fluctuations typically ranging from approximately 2 to 20 feet. The highest water levels occur at the peak of the spring runoff period (i.e., between May and July), with levels receding to a minimum by late summer or early fall. The spot measurements in these wells indicate both the seasonality and the amplitude of annual fluctuations. Continuous water level measurements also show responses to major recharge events.

<sup>1</sup>Universal Transverse Mercator (UTM) coordinates

<sup>2</sup>Screen interval depth from ground surface

<sup>3</sup>Water level depth from ground surface
Figure 3.8-10 shows water table elevation contours for the analysis area computed by the groundwater model calibrated to water levels (Brown and Caldwell 2018a, 2021b). The model calibration statistics (Brown and Caldwell 2021e) indicate that the modeled groundwater elevations compare acceptably to monitoring well water level observations which are concentrated in valley bottoms. There are fewer observation locations for comparison on the mountain side areas. The water table contours mimic the land surface topography. The contours shown indicate that the water table is present both within unconsolidated sediments (particularly in the valley alluvium), and within shallow bedrock (mainly outside of the valley bottoms).

Groundwater horizontal hydraulic gradients within the alluvial deposits range from approximately two to 10 percent and are generally consistent with gradients of adjacent streams. Gradients in shallow bedrock are similar to gradients in the alluvial deposits but are steeper on the mountain slopes outside of the valley bottoms.

Vertical hydraulic gradients were calculated using data collected from 12 well nests (pairs of alluvial and shallow bedrock wells with screens completed at different depths) and multilevel samplers and vibrating wire piezometers installed in bedrock boreholes. Upland areas exhibit strong downward gradients (e.g., MWH-B21), indicating the presence of groundwater recharge areas outside of the mountain valleys, while the valley bottoms exhibit weak upward or downward gradients (SPF 2017). The lack of strong upward gradients along the valley axis may indicate an absence of a larger scale, deeper groundwater system of a type described by Winter (1976) with recharge zones coinciding with high mountain ridges and slopes and discharge zones located in mountain valleys. Low permeability of the underlying bedrock likely prevents development of such a system in the analysis area.

Accumulated baseline groundwater level data indicate that the streams in the analysis area are primarily gaining and groundwater flow near the valley bottoms is angled (in the downstream direction) toward the gaining streams (SPF 2017).

In summary, groundwater flows follow the land surface topography, with most groundwater migrating at shallow depths down the mountain slopes and along the valley bottoms, and eventually discharging to surface streams. On a more local scale, the flow also is affected by distribution of recharge, geology, and existing anthropogenic features (e.g., mine workings).

**Hydrogeologic Units**

The major hydrogeologic units in the Analysis Area and their estimated hydraulic conductivity values are summarized in Table 3.8-10 (Brown and Caldwell 2017a, 2021e, 2021g; SPF 2017). The hydrogeology of the Analysis Area consists of basement intrusive rocks of the Idaho Batholith partially overlain by metasedimentary rocks in the eastern portion of the Analysis Area. The most common intrusive rock in the mine area is granodiorite and the metasedimentary rocks are comprised of quartzites, marbles, dolomites, and schists. Younger volcanic intrusives are located within the Idaho Batholith rocks and metasedimentary rocks, and the bedrock is overlain by alluvium, with the thickest covers (up to approximately 250 feet) located in the valley bottoms.

Other Data Sources: Brown & Caldwell, Perpetua, USGS
Alluvial aquifer pumping tests were performed in 1989, February 2012, December 2013, and December 2019 at the Stibnite Gestrin airstrip well located close to Meadow Creek, about 2,500 feet upgradient from the Meadow Creek–East Fork SFSR confluence, to establish alluvial aquifer characteristics in areas most likely to be impacted by mine operations. In 1989, the well was pumped at a constant rate of about 114 gallons per minute (gpm) for 300 minutes. In February 2012, the well was pumped for 480 minutes at rates ranging from 46 gpm (average for first 15 minutes) to 208 gpm (average for last 100 minutes of test). Those were the preliminary tests and the results of analysis completed using the collected data were considered uncertain (Brown and Caldwell 2017a). A more comprehensive test on the Gestrin well was conducted in December 2013. During the 2013 test, the well was pumped at an average rate of about 100 gpm for almost 31 days. Groundwater levels were monitored during the 2013 test in five alluvial wells and three shallow bedrock wells. Analyzing drawdown data collected from observation wells completed in the alluvium and bedrock allowed hydraulic properties to be estimated for both formations. Hydraulic conductivities estimated from the 2013 test data are 10.2 feet/day for the alluvial aquifer and 4.5 feet/day for the shallow bedrock. These results provide documentation of groundwater productivity of the alluvial sediments and the shallow bedrock in the area of the Gestrin well (Brown and Caldwell 2017a; SPF 2017).

In December 2019, the Gestrin well was pumped for a three-day period at a rate of 60 gpm. The diminished water production from this well between 2013 and 2019 was attributed to well inefficiency, and the 2013 test results were retained as representative of the system and its responses (Brown and Caldwell 2021f). However, data from observation wells during the 2019 pump test was informative in examining the response to alluvial groundwater pumping in the broader area around the Gestrin Well.

Pump based aquifer tests of the four SGP production wells (Stibnite’s Hooterville and main camp domestic wells, Hecla’s Pioneer well, and the Stibnite Plant utility well) completed in 1994 in the alluvium of the East Fork SFSR provided transmissivity values ranging from 67 to 134 feet/2/day. Given an average aquifer thickness of 20 feet in the area of those tested wells, the calculated hydraulic conductivities range from 3.3 to 6.7 feet/day (Brown and Caldwell 2017a).

Source: SPF 2017; Brown and Caldwell 2021g
A pump test of the new Camp Well (SPF 2017) conducted in 2012 provided hydraulic conductivity of 12 feet/day, calculated from transmissivity of 350 feet²/day and a given average thickness for the alluvial aquifer (around the Camp Well) of 30 feet.

In addition to the pumping tests, slug tests conducted in 1996 in two alluvial monitoring wells produced hydraulic conductivity estimates averaging 4.9 feet/day. Additionally, nine slug tests conducted in 2012 on wells completed in various unconsolidated materials at proposed locations for the SGP features including the Yellow Pine pit area (six tests), Hangar Flats pit area (two tests), and proposed tailings disposal area (one test) provided estimation of hydraulic conductivities ranging from 0.3 to 139 feet/day. Slug tests conducted in 2013 in eight alluvial monitoring wells allowed estimation of average and median hydraulic conductivity values of 11.3 feet/day and 7.3 feet/day, respectively. The range of measured/estimated values was 2.8 to 28 feet/day.

Overall, the results reported by the investigations (from 1989 to 2013) for the alluvial groundwater system indicate hydraulic conductivity ranging from 1 to 100 feet/day, with an average of approximately 10 feet/day (SPF 2017).

Hydraulic characteristics of the portion of the regional Idaho Batholith rocks in the Analysis Area have been assessed via 45 packer tests conducted in exploration boreholes, seven slug tests, 11 air lift or well development monitoring of bedrock monitoring well installations, plus one observation of bedrock discharge from the DMEA tunnel (Brown and Caldwell 2021g). These data represent 64 relatively localized observations of the Idaho Batholith rocks' hydraulic properties. In general, packer test results returned lower hydraulic conductivity measurements than the other test methods which tested larger subsurface intervals in boreholes. This is consistent with the interpretation that fracture flow represents the primary flow mechanism within the Batholith rocks, as smaller interval packer tests had less probability of encountering a conductive fracture.

Hydraulic conductivity measurements ranged between 0.0003 and 6.3 feet per day with a geometric mean measurement of 0.02 feet per day, indicating that bedrock conductivity is minor compared to alluvial conductivity. Measurements were laterally consistent across the mine area and generally decreased with depth in the borehole (Brown and Caldwell 2021g).

A long-term pumping test has not been completed in the deeper bedrock portions of the Idaho Batholith rocks in the Analysis Area as zones of groundwater inflow at depth sufficient to sustain a multi-day constant rate test have not been typically encountered in drillholes (Brown and Caldwell 2021g). Monitoring of shallow bedrock rock portions of the Batholith rocks during alluvial pumping tests exhibit bedrock responses to drawdown and depressurization in the overlying alluvium. Responses of bedrock wells to alluvial pumping at the Gestrin Well in 2019 indicate hydraulic conductivities between 1.2 and 4.5 feet/day in the transition zone from alluvium to shallow bedrock where bedrock fractures would be more prevalent than at depth (Brown and Caldwell 2021f).
Hydraulic characteristics of the metasedimentary rocks have been assessed via 16 packer tests conducted in exploration boreholes and six slug tests of bedrock monitoring well installations, (Brown and Caldwell 2021g). These data represent 22 localized observations of the metasedimentary units’ hydraulic properties. Unlike the Idaho Batholith rocks, packer test and slug test results yielded comparable hydraulic conductivity measurements, indicating that the overall permeability of the units is higher than in the underlying Batholith rocks.

Hydraulic conductivity measurements in the metasedimentary units ranged between 0.02 and 5.9 feet per day with a geometric mean measurement of 0.3 feet per day, confirming that the metasediment conductivity is minor compared to alluvial conductivity but more conductive than the Idaho Batholith rocks. Measurements were laterally consistent across the mine area and generally decreased with depth in the borehole (Brown and Caldwell 2021g).

**Groundwater Budget**

A groundwater budget is a basic accounting of the inflows and outflows from a hydrologic system in a specific area. Water budgets provide a means evaluate the availability and sustainability of a water resource. Under existing conditions for the Analysis Area, the predominant inflow component for the groundwater system is recharge from precipitation. The principal groundwater outflow component is discharge of groundwater to surface water along with losses to evapotranspiration in areas where vegetation is utilizing water from a groundwater aquifer.

Locally, stream elevations at most locations are slightly lower than the water table in adjacent areas, suggesting that the streams receive groundwater discharge from the alluvial aquifer. However, there are areas where the opposite is true, indicating the presence of losing stream reaches. For example, groundwater elevations suggest the following losing reaches: 1) on the East Fork SFSR between Garnet Creek and Fiddle Creek; 2) on the East Fork SFSR immediately upgradient of the Yellow Pine pit; and 3) in the lower reach of the EFMC (SPF 2017). In aggregate, there is a net groundwater discharge to streams that represents the most significant groundwater outflow from the system, balancing the input from meteoric recharge.

In a secondary outflow to stream discharge, groundwater from fractured bedrock likely contributes flow to hillside springs located above the alluvial deposits. Springs and seeps near the northerly trending faults along the east side of both upper Meadow Creek and EFMC may be related to these faults (SPF 2017).

**Groundwater Rights**

Existing groundwater rights at the SGP have been acquired by Perpetua and are described in Table 3.8-11.

The existing groundwater rights are specific to historical use. While these are valid water rights, the specific points of diversion, place of use, and beneficial use does not reflect planned SGP activities and would need to be adjusted through the transfer process, and through filing additional applications for permit. These filings were initiated in December 2021.

Groundwater Production Areas

IDWR records indicate that three permitted water supply wells are located at the SGP (Figure 3.8-11). Table 3.8-12 provides a summary information about those wells (Brown and Caldwell 2017a). Anticipated project groundwater supply areas would be in the vicinity of Hangar Flats pit area south of the currently authorized points of diversion (77-7141 and 77-7285) plus in the vicinity of the Yellow Pine pit (Figure 3.8-12). The supply well locations represented on Figure 3.8-12 are preliminary in that specific locations for have not been finalized and will depend on engineering site evaluations to finalize well designs.

ft = feet, bgs = below ground surface.

Groundwater production associated with the SGP would occur in the vicinity of the proposed open pit mine operations and the housing facility (Figure 3.8-12). Most groundwater production would occur in the Hangar Flats pit area both as dewatering pumping and industrial supply well production. Additional dewatering pumping would also occur in the Yellow Pine pit area and to a lesser extent in the West End pit area. There would also be groundwater production from a well located near the worker housing facility.

### 3.9 Surface Water and Groundwater Quality

#### 3.9.1 Introduction

This section describes existing conditions related to surface water quality, groundwater quality, and geochemistry.

#### 3.9.2 Water Quality Resources Area of Analysis

The surface water quality analysis area includes streams and lakes located in the 22 sub-watersheds that encompass the SGP, access roads, transmission lines, and off-site facilities (Figure 3.9-1). Sub-
watersheds are the hydrologic sub-basins that contain smaller tributary stream systems and are defined by the USGS’s 12-digit HUCs (EnviroAtlas 2019; Seaber et al. 1987).

The analysis area for groundwater quality includes the Sugar Creek and Headwaters East Fork SFSR sub-watersheds (Figure 3.9-2), which together encompass the SGP infrastructure that is most likely to influence groundwater quality. The groundwater quality analysis area focuses on the SGP where excavation of mineralized and unmineralized subsurface materials would occur. It does not cover all components, such as off-site facilities or supporting infrastructure corridors, which are limited to surface disturbance activities that would not affect groundwater quality. Based on the hydrogeologic conceptual model for the groundwater quality analysis area, groundwater flow is primarily controlled by topography, with mountain-front recharge flowing through shallow fractured bedrock and colluvium to unconsolidated alluvial deposits, and eventually discharging from the unconsolidated deposits to streams, springs, and seeps. As such, groundwater flow divides likely coincide with the sub-watershed boundaries that define the groundwater quality analysis area (Brown and Caldwell 2018a). The point where groundwater is most likely to flow out of the analysis area is through the alluvial aquifer at the farthest downstream point in the Headwaters East Fork SFSR sub-watershed. Any groundwater leaving the analysis area through this boundary would eventually discharge to the East Fork SFSR downgradient.

The cumulative effects boundaries for water quality are coincident with the area of analysis for direct effects because other current and reasonably foreseeable future activities that could affect water quality conditions are within the same area.

3.9.3 Relevant Laws, Regulations, Policies, and Plans

Land and Resource Management Plan: Physical, social, and biological resources on National Forest System lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. National Forest Land and Resource Management Plans embody the provisions of the NFMA and guide natural resource management activities on NFS land.

In the SGP area, the Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for surface water and groundwater quality and include various objectives, guidelines, and standards for this purpose.

Federal Laws, Regulations, and Policy: Federal laws that apply to water quality include the CWA and the Safe Drinking Water Act. The EPA is responsible for enforcing the federally-mandated CWA. Section 402 of the CWA, which authorizes the National Pollutant Discharge Elimination System (NPDES) permit program, controls water pollution by regulating point sources that discharge pollutants into WOTUS. On June 5, 2018, EPA approved the IPDES Program and authorized the transfer of permitting authority to the state beginning on July 1, 2018. EPA will retain the authority to issue NPDES permits for facilities located on tribal lands and/or discharging to tribal waters.

*Mine Site components are associated with all Alternatives

Note:
Subwatersheds displayed are Hydrologic Unit Code (HUC) 6th level (12-digit)
EPA’s other responsibilities under Section 404 of the CWA include promulgating and interpreting environmental criteria used in evaluating permit applications under Section 404(b)(1): Guidelines for Specification of Disposal Sites for Dredged or Fill Material; coordinating with the USACE (the Section 404 federal permitting authority) in the review of Section 404 permit applications; and sharing responsibility with the USACE in determining the geographic scope of CWA jurisdiction. Section 311 of the CWA also gives EPA regulatory authority with regard to spill prevention, control, and countermeasure plans required for oil storage. Facilities with aboveground and underground storage tanks in excess of specific thresholds are required to develop and implement a SPCC Plan.

Under the Safe Drinking Water Act, EPA has established primary and secondary maximum contaminant levels (MCLs) to protect the public against consumption of drinking water contaminants that present a risk to human health. The MCL is the maximum allowable amount of a contaminant in drinking water that is delivered to a consumer (EPA 2018e, 2018f).

In addition, EPA has established National Secondary Drinking Water Regulations that set non-mandatory water quality standards for 15 constituents. EPA does not enforce these secondary MCLs. They were established as guidelines to assist public water systems in managing their drinking water for aesthetic considerations, such as taste, color, and odor. These constituents are not considered a risk to human health.

State and Local Policy: The IDEQ implements the CWA in Idaho and regulates waterbodies in the state under its jurisdiction to meet Idaho water quality standards that are protective of designated uses and uses that may not be designated. Table 3.9-1 lists the strictest potentially applicable surface water quality criteria used in the water quality analysis in Idaho. These standards represent a combination of human health and cold-water aquatic life criteria that provide a benchmark for evaluating baseline water quality at the mine site and predicted concentration changes resulting from the SGP alternatives.

IDEQ administers the IPDES program regulating discharges of pollutants into WOTUS under its jurisdiction. EPA approved the State's IPDES program in accordance with the Memorandum of Agreement between IDEQ and Region 10 (IDEQ and EPA 2016). Per this memorandum, EPA will oversee IDEQ administration of the IPDES program on a continuing basis for consistency with the CWA, Idaho laws and rules, and all applicable federal regulations (IDEQ and EPA 2016).

Projects that may result in a discharge to WOTUS require Water Quality Certification under Section 401 of the CWA that the discharge is consistent with the CWA and applicable water quality standards. IDEQ is the regulatory authority for Section 401 permitting in Idaho. The IDEQ must grant (with or without conditions), deny, or waive Section 401 certification for any project in Idaho that requires a federal permit or license under the CWA before the federal permit or license can be granted, including the Section 404 permit issued by the USACE. This Water Quality Certification is designed to ensure that a federally-approved project would comply with state water quality standards for surface water and any other water quality requirements under state law.

The CWA also requires the state to prepare a report listing the current condition of all state waters and those waters that are impaired and in need of a total maximum daily load. The first list is referred to as the Section 305(b) list; the second is the Section 303(d) list. Both lists are named in accordance with the
sections of the CWA where they are defined; together, and with additional supplementary information, they are known as the Integrated Report.

Impaired waters on the Section 303(d) list are simply a subset of those on the Section 305(b) list. The current applicable report is IDEQ’s 2018/2020 Integrated Report (IDEQ 2020a).

The Idaho Nonpoint Source Management Plan describes the state’s strategy for addressing nonpoint source pollution collaboratively with local, state, and federal partners, and provides guidance on evaluating and measuring success in meeting water quality goals for the state (IDEQ 2020b). IDEQ’s role in nonpoint source management as it relates to mining and natural resource extraction includes the following:

- Conduct monitoring and total maximum daily load development;
- Conduct site investigations and inspections as necessary;
- Focus on site cleanup and remediation in areas where mining activities have contaminated soils and surface water; and
- Provide technical assistance to responsible state and federal agencies and private organizations/owners as requested.

Under Idaho’s Rules for Ore Processing by Cyanidation (IDAPA 58.01.13), mining facilities that use cyanide in their mineral extraction processes are required to obtain a permit from the IDEQ. IDAPA 58.01.13 establishes procedures and requirement for the issuance and maintenance of permits to construct, operate, and close that portion of a cyanidation facility that is intended to contain, treat, or dispose of process water or process contaminated water containing cyanide. The provisions of these rules also establish requirements for water quality protection which address design, performance, construction, operation, and closure of a cyanidation facility. The rules are intended to ensure that pollutants associated with the cyanidation process are safely contained, controlled, and treated so that they do not endanger public safety or the environment, or interfere with beneficial use of waters of the state.

In addition to regulations enforced by IDEQ, the IDWR regulates stream channels under the Idaho Stream Channel Protection Act. This act requires that a Stream Channel Alteration Permit be obtained from IDWR before any type of channel alteration work, including removal and/or fill and installation of in-water or over-water structures with the potential to affect flow, within the beds and banks of a continuously flowing stream. IDWR, the USACE, and the IDL have established a joint process for activities impacting jurisdictional waterways that require review and/or approval of both the USACE and the State of Idaho. Additionally, IDWR regulates water dams (which may apply to SGP contact water storage ponds) and mine tailings impoundments.

The Idaho Ground Water Quality Rule (IDAPA 2011) establishes minimum requirements for the protection of groundwater by setting standards and beneficial uses and categorizing aquifers to be protected at different levels. The protection levels in IDAPA 58.01.11, summarized in Table 3.9-1, include both primary and secondary numerical groundwater quality standards promulgated by IDEQ to protect human health and the environment. These standards apply to in situ groundwater.

Source: IDAPA 58.01.11; IDAPA 58.01.02; EPA 2018c, 2018f, 2019b

\(^1\) Groundwater standards obtained from IDAPA 58.01.11.
2 Strictest potentially applicable surface water quality standard.

3 The criteria for these metals are hardness-dependent. The values listed are based on the East Fork SFSR hardness of 40 mg/L as calcium carbonate, which represents the 5th percentile hardness during the driest four months at node YP-SR-10 (below the confluence with Meadow Creek) between April 2012 and May 2019.

4 Copper criterion was derived using the Biotic Ligand Model per guidance contained in IDEQ (2017). A conservative chronic copper standard was estimated by applying the lowest of the 10th percentile chronic criteria based on regional classifications for the Salmon River Basin, Idaho Batholith, and third order streams. Per the SGP Water Quality Management Plan (Brown and Caldwell 2020a), preliminary calculations using the Biotic Ligand Model and site-specific data have produced similar values to the standard derived using these regional classifications.

Narrative = No numeric human health standard has been established for beryllium. However, permit authorities will address beryllium in NPDES permit actions using the narrative criteria for toxics in Section 200 of IDAPA 58.01.02, which states: “Surface waters of the state shall be free from toxic substances in concentrations that impair designated beneficial uses. These substances do not include suspended sediment produced as a result of nonpoint source activities.”

s.u. = standard units; mg/L = milligrams per liter; mg/kg = milligrams per kilogram; CaCO3 = calcium carbonate; --- = Indicates no standard for this constituent; P = primary standard; S = secondary standard; d = dissolved fraction; t = total fraction.

CCC= criterion continuous concentration; CMC= criterion maximum concentration; N/A = Not Applicable.

The IDEQ is responsible for coordinating and administering groundwater quality protection programs in the state of Idaho. IDEQ also is responsible for establishing a point of compliance location, if applied for by a mine operator and pursuant to the Idaho Ground Water Quality Rule (IDAPA 58.01.11), where groundwater and surface water downgradient of mining activity must meet established water quality standards. If a point of compliance is not applied for, the mine operator must meet the ground water quality standards in ground water both within and beyond the mining area.

The EPA recommends that a human health methylmercury criteria of 0.3 mg/kg that is translated to a total-mercury concentration of 2 ng/L in surface water be utilized in the analysis. This recommendation is incorporated into the impacts analyses, but table-reported standard values utilize the 12 ng/L (0.000012 mg/L) representing the lowest concentration adopted as a standard.

The Valley County Land Use and Development Ordinances have provisions for well head protection. These regulations would likely apply to any drinking water wells installed. The well head protection regulations control the siting of drinking water wells and prevent wells and their potential capture zones from being installed near potential sources of groundwater contamination.

### 3.9.4 Affected Environment

The affected environment description for water quality is based on water quality data collected by Perpetua, their consultants, and the USGS. Surface water quality and groundwater quality baseline studies were summarized in reports by HDR (HDR 2016a, 2017f). Analytical data presented in the HDR reports were compiled from samples collected over a 4-year period between 2012 and 2016. Additional summary and analysis of the baseline study results were provided in the SGP Water Resources Summary Report (Brown and Caldwell 2017a). Since these initial baseline studies were published, two additional years of data were collected and tabulated in the SGP Water Quality Summary Report, 2012 – 2018 (Midas Gold 2019c), and data collection is ongoing. Additionally, the USGS collected a series of surface water quality samples in the study area between 2011 and 2017, with the study results and data analysis published in two separate reports (Etheridge 2015: Baldwin and Etheridge 2019). Analytical data, statistics, and trends from the USGS and SGP baseline studies were used to characterize existing surface water and groundwater quality at the mine site and are discussed later in this report.
In the Yellow Pine and Hangar Flats ore deposits, precious metals (gold and silver) typically occur in association with very fine-grained disseminated arsenical pyrite \((Fe(S,As)_{2})\), and to a lesser extent, arsenopyrite \((FeAsS)\) (SRK 2017). Antimony occurs as the mineral stibnite \((Sb_{2}As_{3})\) often as along with precious metals mineralization but in deposits that are cross-cutting and generally more confined in distribution. Base metal sulfides (e.g., zinc, copper, and lead) are rare and occur at very low concentrations, at or below typical crustal abundance levels. Various oxidized products derived from weathering of the primary sulfides are associated with the intrusive rocks, including goethite, hematite, jarosite, and scorodite, and these host precious metal mineralization in the oxidized portions of the deposits (M3 2019).

Metasediment-hosted mineralization in the West End deposit has a similar sulfide suite and geochemistry, but with higher carbonate content in the gangue and a much more diverse suite of late-stage minerals. As in the intrusive-hosted mineralization, gold is associated with very fine-grained arsenical pyrite. Antimony mineralization is generally rare in the West End deposit.

The primary intrusive and metasedimentary rock types at the mine site include alaskite, granodiorite (i.e., quartz monzonite), diorite, rhyolite, calc-silicate, carbonates (e.g., dolomite and limestone), quartzite, stibnite stock, schist, breccia, gouge, and granite (SRK 2017). The intrusive rocks associated with the Yellow Pine and Hangar Flats deposits are predominantly composed of quartz monzonite and alaskite. In contrast, the metamorphosed sedimentary rocks of the West End deposit generally consist of calc-silicate, carbonates, quartzite, and schist.

The intrusive and metasedimentary mineralization of the main ore deposits has been extensively drilled during exploration and development, as well as during past mine operations focused on the previously exploited ores. The drilled materials represent the composition of future development rock and ore, as well as historical mine wastes. Samples from these holes were characterized via multi-element total metal analyses and tested for leachable metals (SRK 2017).

Results from the multi-element testing show that arsenic, mercury, sulfur, and antimony are enriched in the Yellow Pine, Hangar Flats, and West End ore bodies. These elements are typically associated with gold deposits (Rose et al. 1979) and their enrichment in the samples reflects the natural mineralization in the area. The enrichment of arsenic, mercury, sulfur, and antimony is generally more pronounced for the ore grade material (with a gold concentration greater than approximately 0.5 gram per ton) as would be expected; however, some of the waste grade material also is enriched with respect to these constituents (SRK 2017).

### 3.9.4.1 Geology and Mineralization

The geochemistry of the mine site is influenced by both the bedrock geology (including naturally occurring mineralization) and a legacy of historical mining activity that has altered the natural environment (Baldwin and Etheridge 2019). Locally, the Yellow Pine and Hangar Flats deposits are hosted by intrusive igneous rock associated with the Atlanta Lobe of the Idaho Batholith. Both deposits are situated along the Meadow Creek Fault Zone, a generally north trending, variably dipping, but near vertical complex fault zone that can be traced from north of the main Yellow Pine deposit south 1.85 miles through the Hangar Flats deposit, and beyond (SRK 2017). The West End deposit is hosted by
metasedimentary rocks of the Stibnite roof pendant located above the Atlanta Lobe of the Idaho Batholith. Figure 3.9-3 illustrates the various lithologic units located within the SGP area (Smitherman 1985, USGS 2007).

Both intrusive igneous rocks and metasedimentary rocks in the SGP area have undergone hydrothermal alteration associated with either Cretaceous magmatic events and/or Tertiary volcanic activity. Potassic and sodic metasomatism and widespread sericitization are characteristic of the earlier hydrothermal alteration event, while silicification and lower temperature hydrothermal alteration occurred in association with tertiary volcanic activity.

### 3.9.4.2 Geochemistry of Mined Materials

Mine operations expose mineralized and altered rocks to air and water and subsequent weathering reactions. Sulfide minerals undergo oxidation reactions that may result in the generation of acidic solutions or pH-neutral metal-bearing solutions that potentially could affect surface water and groundwater resources. Ore mined by the project would be processed on site with tailings placed in a lined TSF. Development rock material generated would be placed in the TSF Buttress or backfilled into the Yellow Pine pit or Hangar Flats pit (Table 3.9-2 and Figure 3.9-4). The SGP also would expose mineralized and altered rock in the walls of the three open pits. This section provides a summary of the geochemical testing results performed to characterize the rock geochemistry of the proposed processed ore, development rock and exposed wall rock in the post-mining quarry.

Data Sources: (SRK 2021)
In addition to the development rock sources included in Table 3.9-2, advancement of the Scout Exploration Decline is expected to produce 25,000 tons of development rock, approximately 0.01 percent of the project’s total mined material. The development rock from the Scout Exploration Decline would consist of the metasedimentary lithologies of the Stibnite roof pendant most prevalent in the West End area including quartzite, carbonate and schists with diorite and quartz monzonite intrusives (SRK 2021a). The development rock from the decline would be destined for the buttress and backfill locations along with the West End pit development rock. Hence, the characterizations of the open pit mined lithologies (Table 3.9-3) are applied to the limited amount of those lithologies present in the development rock from the Scout Exploration Decline.

The geochemical characterization program for mined materials included the following analysis:

- Review of site geology and identification of the primary material types;
- Collection of drill core and coarse reject samples representative of waste rock and ore;
- Collection of tailings representative of processed ore material; and
- Static and kinetic laboratory testing of selected samples.

The following sections describe the material types that would be mined by the SGP as well as the methods and results of the geochemical characterization program.

**Mined Material Types**

Waste rock and ore materials typically are classified and tested according to the material type and the number of samples selected for geochemical testing associated with the relative percentage of each material type expected to be mined following the mine geologic block model (Table 3.9-3 and Figure 3.9-5). The term “material type” for the SGP refers to a site-specific set of rock classifications, primarily within the portion of a lithology where the mining is planned to occur (SRK 2017).

Once open pit mining concludes, the rock types exposed in the Yellow Pine and Hangar Flats pit walls would consist primarily of quartz monzonite and alaskite while the West End pit walls would consist primarily of calc-silicate, quartzite, schist, and carbonate rock types (Table 3.9-3). Backfilling the Yellow Pine and Hangar Flats pits during the closure period will yield exposed rock types above the backfill consisting primarily of quartzite, quartz monzonite, alaskite, and alluvium in the Yellow Pine pit and quartz monzonite, fault gouge, and alluvium in the Hangar Flats pit.

**Multi-Element Analyses**

In addition to the static and kinetic test work, multi-element analyses of exploration samples were available for approximately 46,000 exploration samples collected from drill holes. Multi-element analyses quantify the concentration of metals and analyte concentrations in whole rock samples and represent the relative masses of metals available for leaching from exposed mined materials. When compared to average crustal abundance of analytes (Mason 1966), the local lithologies exhibited enriched concentrations of antimony, arsenic, mercury, and sulfur (Table 3.9-4).

Source: SRK 2017
In addition to whole rock analyses, mineralogical analyses were performed on a subset of rock samples to examine the mineral phases present (SRK 2017). Arsenic and antimony-bearing sulfide minerals such as pyrite, arsenopyrite, and stibnite were detected amongst matric silicate minerals (quartz, microcline, and albite) and carbonate minerals (ferroan dolomite, calcite, and siderite). Minor to major amounts of clay mineralization (illite, muscovite, chlorite, kaolinite, and biotite) were also observed.

**Acid Base Accounting**

Static ABA is an industry recognized method of assessing the potential for acid generation of sulfide-bearing rocks based on the acidification potential of the sulfide minerals and the neutralization potential of carbonates, aluminosilicates, and clays within the rock. The Modified Sobek Procedure (Sobek 1978) method was used, which includes both laboratory analysis and empirical calculations based on the Acidification Potential (AP) and the Neutralizing Potential (NP) (SRK 2017). The AP values are calculated based on sulfide sulfur concentrations in the rock and reported as calcium carbonate equivalents per 1,000 tons of rock. The NP values are determined using a modified Sobek protocol that includes digestion to expel carbon dioxide followed by back titration with sodium hydroxide to a pH of 8.3 and also is reported as calcium carbonate equivalents per 1,000 tons of rock. The difference NP-AP is the Net Neutralizing Potential (NNP). The ratio of NP/AP is the Net Potential Ratio (NPR). The NNP and NPR both characterize the potential for acid generation as a net potential or as a ratio of acid-neutralization to acid-generation, respectively. The ratio has become more favored for use by regulatory agencies because it provides a clearer description of relative quantities of acid producing and acid consuming constituents (MEND 1996).

1NAG testing conducted on a subset of samples where acid-generating potential was uncertain based on ABA analyses.
Siderite (iron carbonate) is a mineral reported in the project deposits. The presence of siderite can result in the overestimation of neutralization potential. Therefore, a subset of samples was submitted for the Siderite Correction Method analyses and those results indicated that the correction was not required for project lithologies.

The ABA analyses indicate that while detectable sulfides are present in all the development rock and ore lithologies (aside from the alluvium), most lithologies are not prone to acid-generation as observed in the paste pH results. Ore samples typically had higher acid-generating potentials than development rock samples due to their higher sulfide concentrations.

**Net Acid Generation Analysis**

Static Net Acid Generation (NAG) tests are conducted to determine the maximum potential for acid generation. The NAG test provides a direct empirical estimate of the overall sample reactivity, including any acid generated by semi-soluble sulfate minerals along with acid generation by sulfide minerals. In this regard, the NAG test differs from the Static ABA test and thus provides another measure of the potential for acid-generation by sulfide and sulfate bearing samples from materials in the SGP lithology.

The method used for NAG testing was that summarized by Stewart et al. (2006). This method involves intensive oxidation of the sample with hydrogen peroxide, which accelerates the oxidation of sulfide and dissolution of sulfate minerals. The leachate is then titrated with sodium hydroxide in two stages (pH 4.5 and pH 7.0) to determine the NAG value. The NAG values are calculated from an equation using the titration results.

NAG testing confirmed that ores from the alaskite, quartz monzonite, granite, quartz monzonite-alaskite, and breccia lithologies had the potential for acid-generation. However, while some individual development rock samples exhibited low potential for acid-generation, the development rock tested was non-acid-generating in aggregate (SRK 2021a).

**Meteoric Water Mobility Procedure (MWMP) Results**

The MWMP test is used to evaluate the leachability of metals from mine material by a laboratory simulation of rainwater leaching in the environment. The MWMP is conducted according to standard test methods (ASTM E-2242-02 [ASTM 1996]) that involve a 24-hour single pass column leach using a ratio of 1:1 for distilled water: rock material. The resulting leachate is analyzed for metals and other analytes of interest. Because materials tested in the procedure must be crushed to a finer state than would occur in field-scale mined materials in order to accelerate reactions in the laboratory, the MWMP results provide a qualitative evaluation of potential leachability of material types. The MWMP test is best applied to oxidized materials as it does not account for changes in pH resulting from long-term oxidation reactions because it is a single pass test.
MWMP tests were run on samples collected from subsurface drill cores and on samples collected from weathered rock exposures on site (Tables 3.9-6a and 3.9-6b). Tests on core samples had circumneutral pH with low total dissolved solids (TDS) with concentrations below 280 mg/L. Effluent concentrations of aluminum, antimony, arsenic, and mercury frequently exceeded their respective most stringent water quality criteria while concentrations of other analytes were generally not detected at concentrations above their criteria (SRK 2017). Tests on weathered surface materials also had circumneutral pH with the exception of one sample of alaskite material that had an acidic pH of 3.8. Leached TDS concentrations from the weathered rock were generally higher than those from core samples ranging between 77 mg/L and 630 mg/L for non-acidic leachate and 2,300 mg/L for the acidic alaskite sample. Like the tested cores samples, effluent concentrations of antimony, arsenic, and mercury were generally above criteria. However, aluminum concentrations were low or below reported detection limits except for the acid-generating sample. This suggests that the leachable mass of aluminum is exhausted more readily in exposed rock than the leachable masses of antimony, arsenic, and mercury.

Tailings Decant Solution Chemistry

Decant solution chemistry for five samples of synthetic tailings materials representative of the different ores that would be processed during the project lifetime yielded circum-neutral to alkaline pH values between 7.2 and 9.4 (Table 3.9-7). Several constituents in the decant solutions were present at concentrations above their most stringent potentially applicable criteria including antimony, arsenic, mercury, sulfate, and TDS (SRK 2021b). Residual cyanide in the tailings was measured in two of the five tests. Constituent concentrations from Yellow Pine pit and Hangar Flats pit decant solutions were generally higher than the concentrations in the West End pit decant solution, consistent with the lower total concentrations of these analytes in the West End ore based on whole rock analyses (Table 3.9-4).

All concentrations are for dissolved constituents unless otherwise noted.

<sup>1</sup> Weighted consolidation water chemistry is a weighted average of the five decant solution samples, with chemistry weighted according to the production of each tailings stream during the entire mine life. For parameters that are below detection for all five samples, the parameter was excluded from the weighted consolidation water chemistry. For parameters that have one or more value below detection, the detection limit was used in the calculation of the weighted consolidation water chemistry.

<sup>-</sup> Indicates parameter was below analytical detection limits in all samples and was not included in the model input.
**Humidity Cell Test Results**

The Phase 1 and Phase 2 HCT cells were operated for between 98 and 184 weeks to achieve stable effluent chemistry. The methodology for humidity cell testing calls for a test duration of 20 weeks. In practice, HCT cells are run until their effluent chemistries stabilize and the potential for acid-generation can be conclusively determined. The termination of each HCT test for the SGP was approved by the Forest Service once these conditions were met. Leachate from each of the HCTs was circum-neutral to moderately alkaline, with pH values ranging from 6.5 to 9.1. The effluent pH also was stable for each of the test cells, indicating that acid generation did not occur, or that the available neutralizing potential was sufficient to offset any acid generation. SRK (2017, 2021b, 2021c) also found that the consumption of neutralizing potential was slow in each of the HCT cells, with over 80 percent of the initial neutralizing potential remaining when the cells were terminated. This indicates that significant buffering capacity is still available and/or that acid generation is limited or occurs at a slow rate despite relatively high sulfide concentrations in the tested samples. These results are consistent with observations from the site. Historic waste rock and tailings have been left at the surface for decades (a duration more than 50 years longer than the proposed SGP mine life), with little evidence of acid rock drainage (SRK 2017).

Despite the finding of low acid generation potential, a few metals constituents still proved to be leachable from the HCTs under neutral to alkaline pH conditions (Table 3.9-8). A few constituents are mobile under these neutral to alkaline pH conditions, including aluminum, antimony, arsenic, manganese, and mercury, which were frequently leached at concentrations above the strictest potentially applicable surface water quality standard. In addition, sulfate, selenium, TDS, copper, cadmium, and zinc were occasionally elevated above the respective water quality criteria. Concentrations of beryllium, bismuth, boron, cadmium, chromium, cobalt, lead, lithium, molybdenum, nickel, selenium, silver, tin, titanium, and vanadium were at or below the strictest potentially applicable water quality criteria in the HCT leachates, indicating a low potential for leaching of these constituents (SRK 2020, 2021c).

HCT analytical results were utilized in developing modeling source terms for the water chemistry predictions. In the development of source terms, the initial flushes from the HCTs were not utilized (SRK 2018) because the first flush chemistries would be indicative of material leaching during the mine operating period, when leachate would be collected as contact water for water treatment or would be expected to dissipate in the near-term due to dilution and/or solubility controls. For the principal constituents of interest, antimony and arsenic, HCT concentrations from the first 12 weeks of testing were compared concentrations derived from the long-term testing. First flush antimony concentrations ranged between one half and twelve times the long-term antimony concentrations while first flush arsenic concentrations ranged between one half and five times the long-term arsenic concentrations. In aggregate, retaining first flush concentrations in the source term calculations would result in higher predicted model concentrations. However, predicted antimony and arsenic concentrations are above the strictest potentially applied water quality standard regardless of assumptions applied to first flush HCT chemistry.

**Potentially Acid-Generating Material Threshold**

The threshold developed to identify PAG material was established to be NPR = 1.5. This value falls between the MEND Prediction Manual for Drainage Chemistry from Sulfidic Geology Materials (MEND
2009) thresholds for PAG (NPR < 1) and non-PAG (NPR > 2). This value was verified through examination of the ABA, NAG, and humidity cell test data where samples with NPR > 1.5 did not yield acidic pH in their paste pH, NAG pH or humidity cell effluent. Further, none of the samples with NPR < 1.5 generated acidity when tested via kinetic tests. However, humidity cell tests of these materials also exhibited higher concentrations of calcium, magnesium, and sulfate in their effluent, suggesting that acid-generating and acid-neutralization reactions were occurring within the test sample. Therefore, the NPR = 1.5 threshold was selected to identify PAG material (SRK 2018, Figure 3-5).

3.9.4.3 Geochemical Influence of Historical Mining Wastes

Mining and mineral processing, primarily of gold, antimony, and tungsten, have occurred at and in the vicinity of the mine site intermittently since the early 1900s. Historical features at the mine property are shown on Figure 3.9-6. The types of waste generated by past mining activity include spent ore (i.e., material that has been leached or otherwise processed to recover metals) in the SODA and heap leach pads, tailings (i.e., Bradley tailings), and waste rock in the Bradley and West End dumps. These historical mining wastes have created geochemical and legacy impacts typical for this type of mining district that are part of the affected environment. The following sections describe the geochemical influence of the historical mining wastes on water quality.

Locally, concentrations of antimony, arsenic, mercury, and cyanide in surface water are potentially attributable to the geochemistry of historical mining wastes present at the mine site (URS 2000b). In the late 1990s, concentrations of antimony and arsenic in Meadow Creek were highest immediately below the historical Bradley tailings deposits in the lower Meadow Creek valley, suggesting that the Bradley tailings provide a continuous source of antimony and arsenic in Meadow Creek (URS 2000b). This conclusion also is supported by recent data collected during Perpetua’s surface water quality baseline study, which indicate that dissolved antimony concentrations in Meadow Creek increase from an average of 0.32 micrograms per liter (µg/L) at YP-T-33 above the SODA (Figures 3.9-7 and 3.9-8) to 6.1 µg/L at YP-T-27 below Keyway Marsh. Average dissolved arsenic concentrations also increase along this stretch from 1.2 µg/L at YP-T-33 to 34.8 µg/L at YP-T-27 (Midas Gold 2019c). Farther downstream in Meadow Creek and the East Fork SFSR, average dissolved arsenic concentrations vary by location (Figure 3.9-9), but average dissolved antimony concentrations continue to increase, reaching a high of 31.0 µg/L at East Fork SFSR assessment node YP-SR-4 below the Yellow Pine pit area. The increase in dissolved antimony concentrations downstream of YP-T-27 occurs due to multiple factors including seeps and springs emanating from historical mining features; metals leached from spent ore and waste rock; in situ mineralization traversed by Meadow Creek (i.e., the Hangar Flats deposit), and other naturally occurring mineralization present throughout the East Fork SFSR drainage.

Mercury concentrations are not similarly elevated by the mine tailings and waste rock, despite periodically exceeding the strictest potentially applicable surface water quality standard (Figure 3.9-10). Although elevated concentrations of mercury are observed in Sugar Creek, these concentrations have a well-documented source in the upstream Cinnabar (mercury) Mine located outside the proposed SGP mine area. Sugar Creek also traverses known mineralized occurrences (based on outcrop) along its length.

Bradley tailings are present in both upper Meadow Creek valley and lower Meadow Creek valley, where the tailings have been covered with approximately 40 feet of waste rock, alluvial fill material, and neutralized “spent” ore material (URS 2000b). Groundwater hydrology studies have indicated that, in 1997 and 1999, the alluvial aquifer water table elevation was high enough to contact the bottom of the historical Bradley tailings deposit throughout most of the Meadow Creek valley (URS 2000b). Elevated concentrations of dissolved arsenic (over 12,000 µg/L) and dissolved antimony (over 1,000 µg/L) were associated with groundwater wells screened completely or partially in the Bradley tailings material, suggesting that the historical Bradley tailings currently present throughout the Meadow Creek valley have an adverse influence on groundwater quality within the mine site. A more recent study (Brown and Caldwell 2017a) also found elevated arsenic and antimony concentrations in groundwater near the Bradley tailings and former leach pads, with concentrations higher in the alluvial aquifer than in bedrock. The water quality of nearby seeps associated with the Bradley tailings, SODA, and Keyway Dam also was elevated in metals, an indication that historical mining features are impacting the alluvial and bedrock aquifers.

In the East Fork SFSR valley below Meadow Creek, alluvial and bedrock water quality samples show multiple locations where arsenic and antimony are elevated above applicable groundwater quality standards. Arsenic concentrations tend to be higher in the bedrock aquifer than the alluvium. The higher concentrations of arsenic in bedrock groundwater where little mining activity has occurred may reflect naturally occurring arsenic sources derived from unmined mineralized zones (Brown and Caldwell 2017a).

Historical mining activity at the mine site has contributed to the development of artificial groundwater seeps from tailings, waste rock piles, and adits. Many of these features have been present at the mine site for decades and have been sampled recently as part of baseline monitoring efforts. Natural springs and seeps also occur where bedrock faults and fractures intersect the ground surface outside the influence of tailings and historical mining features (Figures 3.9-6 and 3.9-7).

Data from the mine spoil seeps have been compared to natural seeps. The results of this comparison indicate that at least some of the metals found in the mine spoil seeps are endemic to the region, particularly antimony and arsenic, which were found to exceed the applicable water quality criteria in the majority of natural seep sites sampled (HDR 2017f).

The seeps and springs in the Bradley tailings-impacted areas of the Meadow Creek valley may transport dissolved constituents from groundwater to surface water. Sulfate levels in seeps and springs were variable and ranged from 4 to 136 mg/L, and pH values in the seep and spring water samples ranged from 6.3 to 8.1, indicating that acid rock drainage is not characteristic of the seeps and springs in the mine site area (URS 2000b). Sulfate and pH concentrations in the mine site springs and seeps were similar during the Surface Water Quality Baseline Study, with median values of 42 mg/L for sulfate and 7.2 for pH (Brown and Caldwell 2017a; HDR 2017f). Similarly, in the East Fork SFSR drainage, arsenic and antimony concentrations in seeps and springs are elevated below the Yellow Pine pit and Northwest Bradley waste rock dump, suggesting that these historical mine facilities are responsible for elevated concentrations of arsenic and antimony in discharging groundwater (URS 2000b).
3.9.4.4 Surface Water

For a discussion of the mine site surface water hydrology and the sub-watersheds that comprise the analysis area, see Section 3.8 and the companion Water Quality Specialist Report (Forest Service 2022f).

Operations Area Boundary

This section focuses on quantifying the baseline water chemistry at the 10 surface water assessment node sampling locations (Figure 3.9-7). The discussion of baseline chemistry is organized around the water quality indicators, which include pH, temperature, major cations and anions, TDS, metals, methylmercury, sediment content, and organic carbon. It should be noted that baseline water quality at the mine site is influenced by both natural mineralization and historical mining activity (Baldwin and Etheridge 2019). Locally, remnant features from historical mining include underground mine workings; multiple open pits; development rock dumps, piles, and tailings deposits; heap leach pads and spent heap leach ore piles; contaminated soils from the former mill and smelter sites; former surface water diversions, dams, townsites, and roads; and an abandoned water diversion tunnel (Midas Gold 2016a).

Major Ions, pH, and TDS

The average baseline major ion chemistry for the surface water assessment nodes is summarized in Table 3.9-9. The East Fork SFSR and Sugar Creek sampling locations each exhibit a calcium-magnesium-bicarbonate water type, meaning that calcium and magnesium are the dominant cations in solution, and bicarbonate is the dominant anion. The samples from Meadow Creek had on average a higher relative proportion of calcium and are therefore classified as calcium-bicarbonate water.

Average TDS concentrations also were consistent in the Meadow Creek and East Fork SFSR sampling locations. The average TDS ranged from 56 to 57 mg/L in the Meadow Creek samples and appears to increase downstream in the East Fork SFSR from about 53 mg/L in the farthest upstream reach (YP-SR-10) to 67 mg/L in the downstream reaches. It appears that despite the higher TDS load in Sugar Creek (116 mg/L), the creek does not appreciably contribute to TDS concentrations in the East Fork SFSR, based on the similar average TDS concentrations obtained for the East Fork SFSR sampling points located just upstream (YP-SR-4) and downstream (YP-SR-2) of the Sugar Creek confluence.

Baseline samples from Fiddle Creek exhibited a slightly different water quality signature compared to the East Fork SFSR and Meadow Creek. Although Fiddle Creek is classified as a calcium-bicarbonate water, the creek has a lower proportion of magnesium and a higher proportion of sodium compared to the other monitoring locations. It also has a lower proportion of sulfate and higher proportion of bicarbonate. Some of these differences may be due to the relatively low average TDS concentration observed in Fiddle Creek during the baseline monitoring period (36 mg/L). The low sulfate and TDS concentrations also could point to a lack of mineralized deposits and historical mining-related impacts in the Fiddle Creek drainage, and different lithologies in the catchment area, specifically calcareous rock formations.

Source: Data obtained from Midas Gold 2019c

CaCO₃ = calcium carbonate.

Units are milligrams per liter except for pH, which is in standard units. Values in the table represent the average of sample results collected between 2012 and 2018. Average concentrations for calcium, magnesium, potassium, and sodium represent the dissolved fraction.
West End Creek stands out as having the most notably different major ion signature among the surface water assessment nodes (Figure 3.9-11). During the baseline period, West End Creek surface water exhibited a calcium-magnesium-bicarbonate-sulfate water type. With the exception of chloride and sodium, the West End Creek samples also had the highest major ion constituent concentrations among the surface water assessment nodes considered, with baseline sulfate and TDS concentrations averaging 57 and 209 mg/L, respectively. West End Creek sample point YP-T-6 is located downstream of both the upper and lower historical West End waste rock dumps; it is therefore possible that the water chemistry at this location has been influenced by the waste material, especially where the creek flows directly through historical development rock piles. Mapped metamorphic bedrock in the West End valley (including marble, quartzite, and schist) in contrast to granitic batholith rocks in the East Fork SFSR drainage also may affect the stream chemistry, as these rock types locally tend to produce higher TDS and alkalinity (SRK 2017).

Field-measured pH values for the surface water assessment nodes were generally in the range of 7 to 8 standard units. The highest average pH (8.4) was observed at West End Creek sample location YP-T-6. Elevated baseline pH measurements at this location are likely another indicator of the geochemical influence exerted by legacy waste rock material, natural mineralization, and the predominance of carbonate bedrock in the West End Creek drainage. Overall, the neutral to alkaline pH values observed in streams near the mine site show that the geochemistry of the natural mineralized deposits and the legacy mine materials is not conducive to acidic drainage.

**Constituents of Interest**

The Surface Water Quality Baseline Study (HDR 2017f) showed that most metals analyzed in mine site streams occur at concentrations that are below the strictest potentially applicable surface water quality standard. Exceptions include antimony, arsenic, and mercury. Therefore, these metals were selected as constituents of interest because of their potential to exceed regulatory standards and impact water and biological resources. Naturally occurring mineralization and historical mining activity have resulted in surface water quality impairments for these constituents (Baldwin and Etheridge 2019). As such, recent surface water baseline studies conducted by both Perpetua and USGS have attempted to characterize antimony, arsenic, and mercury concentrations in the Headwaters East Fork SFSR and Sugar Creek sub-watersheds.

Monitoring by Baldwin and Etheridge (2019) found that antimony in mine site streams primarily occurs in the dissolved phase (primarily as Sb(V); Dovick et al. 2016) with lower antimony concentrations recorded during high flow periods, suggesting a groundwater source. Figure 3.9-8 illustrates the range in dissolved antimony concentrations for stream monitoring locations sampled during the Surface Water Quality Baseline Study (HDR 2017f). Data for seeps in the Meadow Creek, East Fork SFSR, and Sugar Creek valleys also are provided on the figure for comparison. The stream and seep sample locations are organized from upstream (left) to downstream (right) on the horizontal axis of the figure. Overall, the figure depicts increasing dissolved antimony concentrations from upstream to downstream across the mine site.
Figure 3.9-11
Tri-Linear Diagram of Average Major Ion Chemistry for Surface Waters
Stibnite Gold Project
Stibnite, ID
As shown on Figure 3.9-8, average dissolved antimony concentrations are generally below the strictest potentially applicable surface water quality standard in the upper East Fork SFSR drainage. In the Meadow Creek drainage, dissolved antimony concentrations are higher, possibly due to loading from seeps associated with historical mining materials and/or the presence of natural mineralization in adjacent bedrock. The seeps in Meadow Creek valley had the highest concentrations of dissolved antimony across the site. Below the confluence with Meadow Creek, both the stream and seep sample locations in the middle East Fork SFSR drainage generally exhibited dissolved antimony concentrations above the strictest potentially applicable surface water quality standard. Exceptions included tributary sample locations associated with Fiddle Creek (YP-T-11 and YP-T-12) and Hennessy Creek (YP-T-41). In the Sugar Creek valley, which flows across historically mined areas and natural mineralization, seep samples typically contained dissolved antimony above the strictest potentially applicable water quality standard, but the surface water dissolved antimony concentrations tended to be lower due to dilution of the seep inputs. Below the confluence with Sugar Creek, the average dissolved antimony concentration in the East Fork SFSR at monitoring location YP-SR-2 was found to be 21.9 µg/L, which is above the strictest potentially applicable surface water quality standard. This concentration is within the range of average antimony values documented at upstream East Fork SFSR assessment nodes YP-SR-4, YP-SR-6, YP-SR-8, and YP-SR-10 (Table 3.9-10a and 3.9-10b).

Up to 96 percent of arsenic in the mine site drainages occurs in the dissolved phase (primarily as As(V); Dovick et al. 2016), suggesting a groundwater source similar to antimony (Baldwin and Etheridge 2019). Figure 3.9-9 illustrates the trend in dissolved arsenic concentrations for stream and seep monitoring locations sampled during the Surface Water Quality Baseline Study (HDR 2017f). Overall, the dissolved arsenic concentration data exhibit an increasing concentration trend from upstream to downstream across the mine site.

As shown on Figure 3.9-9, average dissolved arsenic concentrations are generally below the strictest potentially applicable surface water quality standard in the upper East Fork SFSR drainage. In the Meadow Creek drainage, dissolved arsenic concentrations increase where Meadow Creek flows past the SODA and former smelter site, presumably due to inputs from seeps and groundwater influenced by historical mining materials. The seeps in Meadow Creek valley had the highest concentrations of dissolved arsenic across the site. Below the confluence with Meadow Creek, both the stream and seep sample locations in the middle East Fork SFSR drainage generally exhibited dissolved arsenic concentrations above the strictest potentially applicable surface water quality standard. Exceptions included tributary sample locations associated with Fiddle Creek (YP-T-11) and Hennessy Creek (YP-T-41), both of which drain less mineralized areas. In the Sugar Creek valley, the seep samples typically contained dissolved arsenic above the strictest potentially applicable surface water quality standard, but the dissolved arsenic concentrations in stream flow tended to be lower. Below the confluence with Sugar Creek, the average dissolved arsenic concentration in the East Fork SFSR at monitoring location YP-SR-2 was found to be 44.5 µg/L, which is above the strictest potentially applicable surface water quality standard.

Source: Data obtained from Midas Gold 2019c
µg/L = micrograms per liter; mg/L = milligrams per liter; ng/L = nanograms per liter.
Avg/Min/Max = sample average, minimum, and maximum.
NC = average value not calculated due to the high percentage of non-detect results.
Values represent the dissolved fraction unless otherwise noted.
Values in the table represent the average of sample results collected between 2012 and 2018. A range of values is provided for sample populations where most results were non-detect.
Based on data from the 10 surface water assessment nodes (Table 3.9-10a and 10b and Table 3.9-11), the average dissolved mercury concentration measured in water samples during the baseline study was calculated to range from 4 to 56 percent of the average total mercury concentration (HDR 2017f). This finding illustrates that, in contrast to antimony and arsenic, mercury primarily occurs in the particulate phase. The association with particles indicates that mercury is derived from erosion and/or re-suspension of surface material, rather than groundwater (Baldwin and Etheridge 2019).

The mean total mercury concentrations for streams and seeps across the mine site are presented on Figure 3.9-10. The figure shows that mean total mercury concentrations were generally below the water quality standard at most of the surface water sampling locations. However, many of the seep sample locations in the Meadow Creek, Middle East Fork SFSR, and Sugar Creek drainages exceeded the regulatory criterion. In contrast, a similar plot for dissolved mercury (Figure 3.9-12) shows that the mean dissolved mercury concentration is below the Idaho surface water quality standard for total recoverable mercury at the majority of locations sampled, further supporting the notion that much of the mercury in the mine site area is associated with particulates.

Values in the table represent the average of sample results collected between 2012 and 2018 for Midas Gold samples, and between 2011 and 2017 for USGS samples.
Figure 3.9-12
Dissolved Mercury Concentrations in Surface Water

Stibnite Gold Project
Stibnite, ID

Data Sources: (HDR 2017)
The surface water assessment nodes YP-SR-10 (East Fork SFSR below Meadow Creek), YP-SR-4 (East Fork SFSR below Yellow Pine pit), and YP-T-1 (Sugar Creek above East Fork SFSR) closely correspond to sample locations EF2, EF3, and Sugar Creek monitored by the USGS (Baldwin and Etheridge 2019). A side-by-side comparison of average dissolved antimony, dissolved arsenic, and dissolved and total mercury concentrations for these sites is presented in Table 3.9-11. Data used to calculate the averages shown in the table were collected between 2011 and 2017 for the USGS locations and 2012 to 2018 for the Midas Gold sample points. Overall, the average dissolved antimony and arsenic concentrations from the two studies are in good agreement, with relative percent difference values between the means of 1.8 to 11.3 percent. Greater variability is evident between the dissolved and total mercury sample averages. The variability in mercury results may be attributable to the generally low concentration values, differing amounts of particulate matter in the total mercury samples, laboratory protocol differences between the two studies, or different runoff conditions in the non-overlapping years sampled (2011 and 2018).

Temporal variations in antimony, arsenic, and mercury concentrations can be correlated to daily mean stream flow (Baldwin and Etheridge 2019). A representative trend plot is provided on Figure 3.9-13 for downstream sampling location YP-SR-4 on the East Fork SFSR below Yellow Pine pit. The figure shows that total and dissolved antimony and arsenic concentrations are inversely correlated to streamflow and tend to be higher during low flow conditions. These findings indicate that groundwater inflows are likely the main source contributing to surface water antimony and arsenic concentrations at the mine site because groundwater discharge to the streams is relatively greater during low flow. The highest concentrations of arsenic are consistently observed during the July to March low flow period. For antimony, the highest concentrations occur near the end of the low flow period as streamflow is beginning to rise during the first flush of spring snowmelt. This first flush phenomenon has been observed at other mine sites and is attributable to the dissolution of soluble salts and the flushing of water concentrated by evaporation (Nordstrom 2009).

Conversely, mercury concentrations are positively correlated to streamflow, with the highest total mercury concentrations occurring during high flow conditions. This relationship indicates that mercury is derived from erosion and resuspension of surface material, which occurs during high flows (Baldwin and Etheridge 2019).

MeHg also was sampled by HDR as part of the Surface Water Quality Baseline Study (HDR 2017f), with additional sampling performed in 2017 and 2018 (Midas Gold 2019c). Sample results for the 10 surface water assessment nodes are provided in Table 3.9-12. Each assessment node was sampled for MeHg 26 to 27 times between 2012 and 2018, with approximately 90 percent of the sample results reported below the method detection limit (<0.1 ng/L). The range of observed MeHg values varied between a minimum of <0.1 ng/L (all sites) to a maximum of 0.64 ng/L (Sugar Creek). Mean MeHg values (calculated using the method detection limit for non-detect results) were at or just above the 0.1 ng/L detection limit.

Source: Data obtained from Midas Gold 2019c
MeHg = methylmercury.
ng/L = nanograms per liter.
Min = sample minimum.
Max = sample maximum.
Values in the table were compiled from sample results collected between 2012 and 2018.

To provide context for the mine site MeHg values, the baseline concentration ranges in Table 3.9-12 were compared to summary statistics from a USGS study of MeHg in U.S. streams (USGS 2009). In this study, the USGS found no statistical difference in surface water MeHg concentrations between previously mined and unmined stream basins. Stream MeHg concentrations across all sites sampled during the study were found to range from <0.010 ng/L to 4.11 ng/L, with a mean concentration of 0.19 ng/L. In most cases, the maximum MeHg concentrations observed in the mine site assessment nodes were less than this nationwide average. Exceptions include the East Fork SFSR above the Yellow Pine area at YP-SR-6 (maximum concentration of 0.20 ng/L), Fiddle Creek (maximum concentration of 0.35 ng/L), and Sugar Creek (maximum concentration of 0.64 ng/L). However, even at Sugar Creek, which has a well-documented upstream source of mercury from the former Cinnabar Mine, MeHg was not detected in 67 percent of the samples collected. The range of results from the Surface Water Quality Baseline Study (HDR 2017f) and subsequent sampling suggests that MeHg concentrations in SGP site streams are not appreciably different from those reported by the USGS nationwide study, and that historical mining activity in the analysis area has not increased MeHg concentrations above those observed at similar reference locations throughout the U.S.

This finding is important because MeHg is present at elevated concentrations in several mine site seeps, as summarized in Table 3.9-13. The calculated means for the seep samples range from <0.1 ng/L to 0.93 ng/L at Smelter Flats Seep (YP-S-5). Maximum MeHg values for the seeps also tend to be higher, reaching 6.6 ng/L at the Smelter Flats Seep (YP-S-5). Despite these relatively high concentrations, the mine site seeps do not appear to significantly influence surface water MeHg levels (e.g., loading), either due to the low seep flow rates compared to surface water flows.

Source: Midas Gold 2019c  
ng/L = nanograms per liter.  
MeHg = methylmercury.  
SODA = spent heap leach ore disposal area.

Other constituents that occur in mine development rock or may be used in ore processing include aluminum, cadmium, copper, total cyanide, iron, lead, manganese, selenium, thallium, and zinc. Baseline concentrations of these constituents measured at the 10 surface water assessment nodes are provided in Table 3.9-10. The table also includes the minimum and maximum concentrations measured for each constituent to illustrate the range of values reported during the baseline study.

**Sediment**

Wildfires in the past have burned much of the forested area at the SGP and vicinity, resulting in increased erosion from the burned areas. In addition, the failure of a water dam on EFMC in 1965 caused extensive erosion both upstream and downstream of the former dam, with deposition of eroded sediment in Meadow Creek and transport of this sediment into the East Fork SFSR continuing to occur.

The ongoing erosion and sediment transport affect the turbidity and Total Suspended Solids (TSS) content of surface water. The dynamics and relationships between turbidity and TSS are functions of watershed-specific factors; but in general, the more TSS in the water, the murkier it appears and the higher the turbidity. **Table 3.9-14** and **Table 3.9-15** provide the TSS (in mg/L) and turbidity (in Nephelometric Turbidity Units, or NTUs), respectively, for the 10 surface water assessment nodes. As shown in the tables, while concentrations of TSS and turbidity are typically low during some months
under existing conditions, seasonal variations occur, and concentrations reach moderate to high levels during high flow periods.

An overview of sediment transport at the mine site also is provided in Etheridge (2015). This study found that much of the sediment entering the East Fork SF SR was derived from Sugar Creek, Meadow Creek, and EFMC (i.e., Blowout Creek). The Meadow Creek reach contributes more sediment than Sugar Creek, but most of the sediment load discharged from the Meadow Creek reach is deposited in the Yellow Pine pit lake (Etheridge 2015). Load modeling by Etheridge (2015) also showed that about 90 percent of coarse-grained sediment derived from upgradient is deposited in the Yellow Pine pit, but over 80 percent of the fine-grained sediment (<0.0625 millimeter in diameter) entering the pit lake passes through and is transported downstream. Thus, the Yellow Pine pit is an effective sediment trap for coarse-grained particles but does not have a long enough residence time to deposit the majority of the fine-grained sediment load.

**Organic Carbon**

No samples were analyzed for organic carbon during the Surface Water Quality Baseline Study (HDR 2017f). However, a previous study by Holloway et al. (2017) found relatively low dissolved organic carbon concentrations (1.1 to 1.7 mg/L) in the East Fork SF SR, Meadow Creek, and Sugar Creek. The dissolved organic carbon concentrations in a watershed can be correlated to vegetation density, vegetation type, and soil composition, with higher vegetation densities and organic-rich soils resulting in higher levels of organic carbon (Camino-Serrano et al. 2014; Larsen et al. 2011; Mzobe et al. 2018). Thus, dissolved organic carbon concentrations are expected to be low in the SGP drainage area containing poorly developed mineral soils and sparse vegetation.

**Temperature**

Stream temperature criteria have been established for chinook salmon, steelhead, and bull trout in the Payette Forest Plan as amended (Forest Service 2003a). IDEQ also has published thermal criteria for salmonid species that vary based on the aquatic life classification of a water body (e.g., warm water aquatic life, cold water aquatic life, salmonid spawning, etc.) (IDEQ 2019c). The IDEQ standards include requirements for Maximum Daily Maximum Temperature, Maximum Weekly Maximum Temperature, and Maximum Daily Average Temperature.

Establishing existing surface water temperature conditions at the SGP was important to provide a baseline dataset for comparing future temperature changes caused by the action alternatives. Two methods for establishing baseline temperatures were used: monthly grab samples and 15-minute temperature measurements. Temperature ranges from both datasets are discussed below; however, the 15-minute temperature measurements are believed to provide a more accurate representation of diurnal temperature variability for comparison to thermal criteria.

A summary of monthly grab sampling temperature statistics is provided in Table 3.9-16 for the surface water assessment nodes. The data and statistics shown in the table were compiled from the Surface Water Quality Baseline Study (HDR 2017f). A review of the monthly temperature statistics indicates that summer monthly stream temperatures are typically highest in July and August, with July temperatures...
ranging from a low of 6.8 degrees Celsius (approximately 44 degrees Fahrenheit) at West End Creek (YP-T-6) to a high of 17.8 degrees Celsius (approximately 64 degrees Fahrenheit) at the East Fork SFSR above Yellow Pine pit (YP-SR-6). Average monthly fall temperatures are highest in September, ranging from 6.7 degrees Celsius (approximately 44 degrees Fahrenheit) at West End Creek (YP-T-6) to 12.7 degrees Celsius (approximately 55 degrees Fahrenheit) at Meadow Creek near the SODA (YP-T-22).

For comparison to the monthly statistics, a graphical depiction of 15-minute temperature measurements is provided for the two-week periods centered on August 1 (Figure 3.9-14) and September 21 (Figure 3.9-15). These dates approximately coincide with the average timing of maximum summer and fall stream temperatures in the SGP area.

The 15-minute temperature data used in the water quality evaluation spans a period of record extending from 2012 through 2017. During this timeframe, 2016 was found to be the year with the warmest summer stream temperatures (Figure 3.9-14). The maximum summer temperatures in 2016 occurred on July 29, slightly before the average date of August 1. Observed conditions during the weekly periods immediately before and after July 29, 2016, therefore represent the period of low-flow, maximum, weekly summer temperatures. The range of observed temperatures across the mine site during this two-week period in 2016 was 7.2 to 19.6 degrees Celsius (approximately 45 to 67 degrees Fahrenheit) (Brown and Caldwell 2018b).

During the fall period, maximum stream temperatures were observed two years earlier in 2014 (Figure 3.9-15). The maximum daily fall temperature in 2014 occurred on September 24, slightly after the average date of September 21. Observed conditions during the weekly period immediately before and after September 24, 2014, therefore represent the period of low-flow, maximum weekly fall temperatures. The range of observed temperatures during this fall period was 6.6 to 15.7 degrees Celsius (approximately 44 to 60 degrees Fahrenheit) (Brown and Caldwell 2018b).

Overall, these weekly summer and fall values offer a better representation of the low flow, maximum seasonal temperatures than the monthly data, and therefore provide a better baseline for comparison to thermal criteria and future predicted temperature increases.

**Impaired Waterbodies**

The federal CWA requires states to prepare a report listing the current condition of all state waters and identifying streams that are impaired because they do not meet their designated beneficial uses. IDEQ’s 2018/2020 Integrated Report (IDEQ 2020a) provides the Section 305(b) list (condition of state waters) and the Section 303(d) list of impaired waters in the State of Idaho. Stream segments identified on the Section 303(d) list are classified as Category 5 waters, defined as waters that do not meet applicable water quality standards for one or more beneficial uses due to one or more pollutants.

Based on data from the 2016 Integrated Report, all inventoried waterbodies at the mine site are classified as Category 5 impaired waters except for West End Creek (which is a Category 2 stream that fully supports its designated uses). A summary of the current designated beneficial uses and causes of impairment for the impaired waterbodies at the mine site is provided in Table 3.9-17. The causes for listing are associated with arsenic, with the East Fork SFSR also being listed for antimony (downstream of Meadow Creek), and Sugar Creek also being listed for mercury. The listed constituents are similar to the constituents of interest identified in the Surface Water Quality Baseline Study (HDR 2017f).

Off-Site Facilities and Access Roads

The Surface Water Quality Baseline Study (HDR 2017f) did not include sample locations outside of the proposed SGP. However, streams adjacent to proposed access roads, utility corridors, and off-site facilities have the potential to be impacted by these SGP activities. The types of impacts that could occur are usually described qualitatively because little is known about the existing water quality of these streams. However, for Category 5 waters that have a 303(d)-listed water quality impairment, it is possible to conduct a more specific analysis evaluating how levels of the impaired constituent(s) may be impacted by SGP activities.

IDEQ has inventoried 11 lakes and 701 different stream segments in the surface water quality analysis area. Of these features, 66 are classified as Category 5 waters. Figure 3.9-16 shows the inventoried stream segments within the analysis area, broken down by “Fully Supporting” beneficial uses (Categories 1 and 2), “Not Assessed” (Category 3), “Not Supporting” beneficial uses (Category 4), and “Not Supporting/303(d) Listed” (Category 5).

In the western portion of the inventory area, waters that are not supporting beneficial uses are concentrated in the agricultural valley that drains towards Lake Cascade (Cascade Reservoir). Causes for the listing of these waters are largely tied to phosphorus and flow regime alteration, with some streams also listed for temperature, sedimentation/siltation, and biota/habitat assessment considerations. Cascade Reservoir is specifically listed for phosphorus and pH.

In the central portion of the inventory area, waters that are not supporting beneficial uses are primarily associated with the SFSR and its tributaries, and Johnson Creek and its tributaries. Causes for listing of the SFSR and tributaries are primarily associated with temperature and sedimentation/siltation; causes for listing of Johnson Creek and tributaries are primarily associated with temperature.

Impaired waterbodies in the eastern portion of the inventory area are primarily associated with the Meadow Creek and upper East Fork SFSR watershed impacted by elevated arsenic concentrations. Water quality impairments for the mine site streams have been discussed above and are summarized in Table 3.9-17.

3.9.4.5 Yellow Pine Pit Lake

A lake has formed in the former Yellow Pine pit where the East Fork SFSR flows through it. The existing pit lake has an estimated maximum depth of 35 feet and an approximately 4.75-acre surface area with a contained water volume of approximately 92 acre-feet. Originally, the pit was excavated to a depth 125 feet below the current water level, but the excavation has filled with approximately 90 feet of sediment (Brown and Caldwell 2017a).

Water chemistry samples were collected in two 1999 sampling events at the surface and bottom of the lake at three locations across the lake from inflow to outlet plus one intermediate depth at the middle location (URS 2000b, Tables 8.1-21, 8.1-22, and 8.1-23). Circumneutral pH values were observed ranging from 7.2 to 8.2 with low TDS concentrations between 47 and 78 mg/L. Analyses of total and dissolved metals indicated that concentrations of most metals were below reported analytical detection limits with the exceptions of antimony, arsenic, iron, magnesium, and manganese. Dissolved mercury was detected in a single sample at 0.23 mg/L but all other dissolved and total mercury analyses (including the companion total mercury analysis for that location) were below method detection limits reported between 0.042 mg/L and 0.063 mg/L. Analyses able to detect mercury concentrations at lower concentrations were not conducted as part of the 1999 investigation. These analytical method detection limits are greater than the strictest potentially applied water quality standard and it is uncertain whether the pit lake water meets that standard.

Concentrations of antimony and arsenic exceeded the strictest potentially applied water quality standards for all samples analyzed with total antimony concentrations ranging between 0.020 mg/L and 0.033 mg/L and total arsenic concentrations ranging between 0.047 mg/L and 0.098 mg/L. There was no clear spatial trend in the antimony and arsenic concentration measurements and total concentrations for these analytes were close to dissolved concentrations. The other metals detected were below the strictest potentially applied water quality standards.

Continuous water temperature data was collected from the Yellow Pine pit lake at locations near its inflow and outflow (Figure 3.9-17; Brown and Caldwell 2021i). These temperature measurements closely resemble stream water temperature measurements collected from USGS Gauges 13311000 and 13311250 upstream and downstream of the lake, respectively (Figure 3.9-18). In general, there are wider diurnal ranges in upstream water temperatures than in the downstream water temperatures, indicating that the Yellow Pine pit lake acts to moderate daily temperature variability.

3.9.4.6 Groundwater

This section focuses on quantifying the baseline groundwater chemistry in areas monitored by the 17 monitoring wells of interest listed in Table 3.9-18 with locations shown on Figure 3.9-19. The discussion of baseline chemistry is organized around the groundwater quality indicators, which include pH, major cations and anions, TDS, and metals.

It should be noted that baseline water quality at the mine site is influenced by both natural mineralization and historical mining activity.
Major Ions, pH, and TDS

Average baseline water quality characteristics measured between 2012 and 2018 for the groundwater monitoring wells of interest are summarized in Table 3.9-18. Calcium tends to be the dominant cation in most of the alluvial monitoring wells with bicarbonate or sulfate dominant anions. As a result, most alluvial wells in the mine site have a calcium bicarbonate water quality signature, but a few wells (MWH-A05, MWH-A07, MWH-A18, and MWH-A19) exhibit a calcium-sulfate water type. The calcium-sulfate wells are located proximal to and immediately downgradient of legacy mining facilities (HDR 2016a). Overall, the major ion chemistry of alluvial groundwater at the mine is similar to surface water, illustrating the interconnectedness between the groundwater and surface water systems.

Most of the bedrock monitoring wells (screened between a range of 208 to 815 feet bgs) also display a calcium-bicarbonate water quality signature. Notably, several alluvial and bedrock well pairs exhibit similar characteristics. Many of the bedrock wells are screened at relatively shallow depths below ground surface near the valley walls where the alluvial aquifer is thinner (HDR 2016a), and the bedrock is hydraulically connected to the alluvium deposits.

Despite the overall dominance of calcium and bicarbonate, the major ion chemistry of the bedrock aquifer tends to be more variable than the alluvium. For instance, samples from bedrock wells MWH-B03, MWH-B04, and MWH-B07 consistently have sodium and bicarbonate as the major cation-anion pair. These wells are screened at deeper depths near the center of the alluvial valleys. In addition, monitoring well MWH-B05 typically exhibits monthly variations in the major ion geochemistry potentially attributable to its shallower screened interval in the bedrock observing the effects of seasonal recharge in the overlying alluvium.

Average TDS concentrations in the groundwater wells of interest are variable but tend to be less than the 500 mg/L Idaho secondary groundwater standard. The average TDS values shown in Table 3.9-18 range from 58 to 465 mg/L for the alluvial wells, and from 60 to 415 mg/L for the bedrock wells.

Field-measured pH values for the groundwater wells of interest were generally in the range of 6.1 to 8.9 standard units. The highest average pH (8.86) was observed in bedrock well MWH-B04. This pH value slightly exceeds the Idaho secondary groundwater standard. Overall, the circumneutral to alkaline pH values observed in groundwater near the mine site show that the geochemistry of natural mineralized deposits and legacy mine materials is not conducive to acidic rock drainage.

Constituents of Interest

The Groundwater Quality Baseline Study (HDR 2016a) showed that several metals are present in mine site groundwater at concentrations that exceed the Idaho primary and secondary groundwater quality standards. The constituents exceeding applicable standards typically include antimony, arsenic, iron, and manganese in alluvial groundwater, and aluminum, antimony, arsenic, and iron in the bedrock groundwater. Therefore, these metals were selected as constituents of interest because of their potential to exceed regulatory standards and impact water and biological resources. Based on Table 3.9-18, average concentrations measured for the monitoring wells of interest are representative of the broader baseline study findings. Data presented in this table show that average concentrations of pH, aluminum, arsenic, iron, manganese, and antimony exceed the groundwater quality standards from Table 3.9-1 at one or more wells.

Source: Brown and Caldwell 2019; HDR 2016a; Midas Gold 2019c; SRK Consulting (SRK) 2018a

1 Represents average chemistry measured during the 2012-2018 baseline period. Concentration values represent the dissolved fraction unless otherwise noted.

2 Bolded values exceed the respective Idaho Groundwater Quality Standard (IDAPA 58.01.11).

TSF = Tailings storage facility.

mg/L = milligrams per liter.

- Indicates no standard for parameter.

* Indicates secondary standard.

< = less than detection limit.
Based on these findings, antimony and arsenic were identified as constituents of interest in groundwater. This determination is supported by the fact that groundwater quality criteria associated with antimony and arsenic were established to protect human health, whereas criteria for iron, aluminum, and manganese are based on secondary standards established to protect aesthetic and cosmetic qualities of drinking water. Mercury was not identified as a groundwater constituent of interest, because both total and dissolved mercury concentrations were consistently reported below the water quality standard in the alluvial and bedrock monitoring wells. Although certain waterways in the Stibnite Mining District have drinking water supply as a designated use (e.g., Meadow Creek, Garnet Creek, Fiddle Creek, and Midnight Creek), and Idaho groundwater quality standards apply throughout the Stibnite Mining District, there are no current, contemplated, or likely future public water supply intakes or wells in the zones at the SGP where metals levels exceed applicable standards. However, the implications of mercury concentrations in groundwater on surface water chemistry was retained as part of the impact analysis.

**Figure 3.9-20** illustrates the trend in dissolved antimony concentrations for groundwater monitoring locations across the mine site. During the baseline study, the fraction of antimony adsorbed onto solid particulates was found to be small, suggesting that the antimony concentration is adequately represented by the dissolved phase of this constituent (HDR 2016a). The figure shows that mean dissolved antimony concentrations are generally below the 6 µg/L Idaho primary groundwater standard in the Meadow Creek valley; however, antimony concentrations increase by two to three orders of magnitude at some of the downgradient alluvial and bedrock wells, such as MWH-A05, MWH-B05, and MWH-A07. Immediately below the confluence with Meadow Creek, groundwater antimony concentrations in the lower East Fork SFSR alluvial aquifer are elevated above the primary groundwater standard but generally decrease in concentration downgradient. The baseline dissolved antimony concentrations exceed the Idaho primary groundwater standard in wells MWH-A14 and MWH-B15 upgradient of Yellow Pine pit. In the Sugar Creek valley, the average dissolved antimony concentration also is above the Idaho primary groundwater standard in bedrock well MWH-B20 near the proposed location of the West End pit.

For most samples collected during the Groundwater Quality Baseline Study (HDR 2016a), 90 to 100 percent of arsenic was found to occur in the dissolved fraction. **Figure 3.9-21** illustrates the trend in dissolved arsenic concentrations for groundwater monitoring locations across the mine site. The figure shows that near wells MWH-A01 and MWH-A03 in the upper Meadow Creek valley, dissolved arsenic is on average higher in the bedrock aquifer than in the alluvium. This trend is reversed farther downgradient in the valley, where monitoring wells MWH-A04 and MWH-A05 have some of the highest average dissolved arsenic concentrations observed during baseline monitoring. The increase in dissolved arsenic in this area is likely due to the influence of historical mining materials.

In both the alluvial and bedrock aquifer, average dissolved groundwater arsenic concentrations were mostly above the primary groundwater standard in the lower East Fork SFSR and Sugar Creek valleys. This includes groundwater monitoring wells MWH-A14, MWH-A15, MWH-B15, and MWH-B20 near Yellow Pine pit.

Overall, dissolved concentrations of antimony and arsenic fluctuate seasonally, but to a lesser extent in bedrock wells than in alluvial wells. Concentrations are generally lower during spring and higher during
the fall. This suggests that the concentrations are being diluted in springtime by freshwater recharge, but that concentrations increase during fall when groundwater levels typically approach seasonal lows.

3.10 Vegetation

3.10.1 Introduction

This section describes the existing conditions of vegetation communities, and botanical resources, and non-native plants in the analysis area. This summary is based on best available information from the Forest Service, IDFG, and USFWS. Additional details and information can be found in the SGP Vegetation Specialist Report (Forest Services 2022g).

3.10.2 Vegetation Resources Area of Analysis

The analysis area covers approximately 17,397 acres of land, with 9,062 acres (52 percent) on the BNF, 4,942 acres (28 percent) on the PNF, 347 acres (2 percent) on the Salmon-Challis National Forest, and 3,046 acres (18 percent) outside Forest Service boundaries. The analysis area is shown in Figure 3.10-1.

The 300-foot buffer was selected to encompass an area where direct and indirect impacts (e.g., dust, impacts to pollinators, etc.) from the action alternatives could impact vegetation.

3.10.3 Relevant Laws, Regulations, Policies, and Plans.

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to vegetation resources. Additional descriptions of these regulations can be found in the SGP Vegetation Resources Specialist Report (Forest Service 2022g).

Land and Resource Management Plan: The Payette and Boise Forest Plans (Forest Service 2003a, 2010a) establish goals, objectives, standards, and guidelines that provide a framework for the analysis of impacts on vegetation, botanical resources (including ESA-listed threatened, endangered, proposed, and candidate species and Forest Service-designated sensitive species), and non-native plants.

The National Forest Management Act: The NFMA requires the Secretary of Agriculture to assess forest lands, develop a management program based on multiple-use, sustained-yield principles, and implement a resource management plan for each unit of the NFS. The NFMA, as amended, and its implementing regulations under 36 CFR 219, consolidate and articulate Forest Service management planning responsibilities for lands and resources of the NFS.

Endangered Species Act: The ESA (16 USC Ch. 35 Section 1531 et seq. 1988) is federal legislation that is intended to provide a means to conserve the ecosystems upon which endangered and threatened species depend and provide programs for the conservation of those species, thus preventing extinction of plants and animals. Aspects of the law pertaining to plants are administered by the USFWS.

**Note:** The McCall - Stibnite Road (CR 50-412) consists of Lick Creek Road, East Fork South Fork Salmon River Road (East Fork Road) and Salmon Road.
Federal Noxious Weed Act: The Federal Noxious Weed Act of 1974 (P.L. 93-629) (7 USC 2801 et seq., 88 Stat. 2148) directs the management of undesirable plants on federal lands, including prohibiting the transport of noxious weeds into the U.S. and between states. This legislation also outlines how noxious weed infestations are to be quarantined and controlled on federal lands. This act also requires agencies to develop programs to eradicate undesirable plants and “establish and adequately fund an undesirable plants management program through the agency’s budgetary process; complete and implement cooperative agreements with state agencies regarding the management of undesirable plant species on federal lands under the agency’s jurisdiction; and establish integrated management systems to control or contain undesirable plant species targeted under cooperative agreements” (7 USC 2418). In addition, federal law requires agencies to consult with state and local agencies to develop a coordinated weed management effort.

Forest Service Manual 2670: FSM 2670 (Threatened, Endangered, and Sensitive Plants and Animals) gives management direction for conservation, management, and recovery of sensitive species on Forest Service-administered lands. This FSM states that sensitive plant species must receive special management emphasis to ensure their viability and to preclude trends toward endangerment that would result in the need for federal listing. Under this guidance, there must be no impacts to a sensitive species without an analysis of the significance of adverse effects on the populations, its habitat, and on the viability of the species in the planning area (for this analysis, the planning area is a Forest in which a species occurs).

Forest Service Manual 2900: FSM 2900, Invasive Species Management, sets forth NFS policy, responsibilities, and direction for the prevention, detection, control, and restoration of effects from aquatic and terrestrial invasive species (including vertebrates, invertebrates, plants, and pathogens).

U.S. Department of Agriculture Departmental Regulation 9500-004: USDA Departmental Regulation 9500-004 outlines USDA’s responsibility “to help maintain sufficient and efficient production capability of farm, forest, water, and rangeland resources for the public benefit, now and in the future, and to encourage and support proper use, management, and conservation of those natural resources” (USDA 2008). This Departmental Regulation was established to describe the USDA’s goal of improving fish and wildlife habitats where needed and ensuring the presence of diverse, native, and desired nonnative populations of wildlife, fish, and plant species (USDA 2008). Impacts to rare plant species in the analysis area, including those designated as forest watch species, are included in the analysis to determine adherence to this regulation.

The Sawtooth and Boise National Forests Invasive Species Project Final Environmental Impact Statement and Record of Decision: The Sawtooth and Boise National Forests Invasive Species Project FEIS (Forest Service 2019a) documents the analysis conducted for the Sawtooth and Boise National Forests Invasive Species Project. The overall purpose of the proposed action was to reduce the negative effects of existing and future invasive plants on the structure and function of native plant communities and on other natural resource values within the administrative boundaries of the Sawtooth and Boise National Forests. The ROD for this project (Forest Service 2019b) documents selection of the EIS proposed action to eradicate or control existing or newly discovered invasive plants using an integrated weed management strategy.

The South Fork Salmon River Subbasin Noxious and Invasive Weed Management Program EIS and RODs: The SFSR Subbasin Noxious and Invasive Weed Management Program EIS (Forest Service
2010c) was developed to evaluate and disclose the impacts of alternative management strategies to manage noxious and invasive weeds in the SFSR subbasin outside the FCRNRW on the PNF and BNF. The PNF and BNF each issued separate RODs for this EIS for portions of the project on lands within their respective jurisdictions (Forest Service 2007a, 2010d). Both Forests selected the preferred alternative (Alternative C), though the BNF ROD included modifications to the preferred alternative.

In accordance with the Federal Noxious Weed Act, the SFSR Subbasin Noxious and Invasive Weed Management Program was implemented by the PNF in 2007, and BNF in 2010. The purpose of this program is to develop criteria to prioritize weed species and treatment areas in the SFSR subbasin; Identify and treat existing priority weed infestations in the SFSR subbasin on the PNF and BNF using a variety of methods including herbicide application; Prevent or limit the introduction and establishment of identified weed species, particularly in areas at high risk due to recent fires; and Restore and maintain native plant communities and protect the natural functioning condition and native biodiversity of ecosystems in the SFSR subbasin.

Executive Orders 13112: EO 13112 requires that federal agencies prevent the introduction and spread of invasive species, detect and respond rapidly to control such species, monitor invasive species populations, and restore native species and habitat conditions in ecosystems that have been invaded. In addition, the order requires a federal agency to “not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species.”

Idaho Invasive Species Act of 2008: The Idaho Invasive Species Act of 2008 provides policy direction, planning, and authority to combat invasive species infestations throughout the state and to prevent the introduction of new species that may be harmful. This act defines the different classes of weeds and sets priority for their containment and eradication.

Idaho Statute Title 22, Chapter 24 (22-2407): Idaho Statute Title 22, Chapter 24 (22-2407) outlines landowner and citizen duties for controlling and treating noxious weeds on public and private land.

The Idaho Department of Agriculture Administrative Rule 02.06.09: The Idaho Department of Agriculture Administrative Rule 02.06.09 governs the designation of invasive species, inspection, permitting, decontamination, recordkeeping, and enforcement of regulated invasive species, including invasive plant species defined under the Idaho Plant Pest Act of 2002.

Valley County Regulations: Valley County administers noxious weed control and monitoring under Idaho Statute Title 22, Chapter 24 (22-2407).

3.10.4 Affected Environment

3.10.4.1 Vegetation Communities

Forest Potential Vegetation Groups in the Analysis Area within Forest Service-Managed Land

The Forest Service maps PVGs in the PNF and BNF and updates this information periodically (most recently in 2005 for the PNF and 2017 for the BNF). This mapping is available only for NFS lands.
Approximately 347 acres (2 percent) of the analysis area occur in the Salmon-Challis National Forest (administered by the PNF); however, PVG data were not available for this area.

In Forest Service mapping, PVGs are forested habitat types that share similar environmental characteristics, site productivity, and disturbance regimes. PVGs are generally a description of the climax plant community that could be supported by a site, as determined by abiotic conditions such as climate, soil types, hydrological conditions, and topographical aspect. The extent (in acres) of PVGs in the analysis area is presented in Table 3.10-1. Descriptions and maps of PVGs in the analysis area are presented in Appendix A of the SGP Vegetation Specialist Report (Forest Service 2022g).

The existing vegetation map layer can be used to describe seral-stage (intermediate ecological succession) plant community composition as it was at the time of the most recent mapping. Note that information in existing vegetation mapping has not been verified on-the-ground within the analysis area; however, an accuracy assessment is associated with this mid-scale map.

Existing vegetation mapping typically describes the current dominant vegetative cover or species occupying a site and is frequently updated to reflect vegetation changes due to disturbance such as fire, insects, and disease. In general, existing vegetation types in the analysis area are coniferous forests typical of high mountain regions in Idaho and the inland northwestern U.S. The most common existing vegetation types in the analysis area are lodgepole pine (*Pinus contorta*) forests, subalpine fir (*Abies lasiocarpa*) forests, Douglas-fir (*Pseudotsuga menziesii*) forests, ponderosa pine (*Pinus ponderosa*) forests, and Engelmann’s spruce (*Picea engelmannii*) forests. Other vegetation types include grand fir (*Abies grandis*) forests, aspen (*Populus tremuloides*) forests, and whitebark pine (*Pinus albicaulus*) forests. Fires routinely occur in the analysis area and surrounding forests, and as such, much of the analysis area and vicinity is now mapped as burned herblands (grasses and forbs), burned sparse vegetation, and burned forest shrublands reflective of earlier seral stages.

A mature limber pine (*Pinus flexilis*) stand occurs in the area of the SGP (2019 Whitebark Pine Survey Report [Tetra Tech 2020b] for a map of this location). Although limber pine has no listing status in the state of Idaho, mature limber pine trees are uncommon in the surrounding Forests, and this may be the only documented population of this species on the PNF (Mancuso 2016). This stand overlaps various PVGs mapped as PVG 7 - Cool Dry Subalpine Fir (overlap of 8.8 acres), PVG 10 - Persistent Lodgepole Pine (overlap of 25.8 acres), PVG 11 - High Elevation Subalpine Fir (overlap of 0.7 acre), and areas not successional to forests (overlap of 7.8 acres).

**Non-Forested Vegetation Groups in the Analysis Area within Forest Service-Managed Land**

PVG mapping has identified some acreages in the analysis area as not being successional to forests. Acreages of existing vegetation mapping within these areas are presented in Table 3.10-2. As PVG mapping and existing vegetation mapping are performed using different processes and have different objectives, forest vegetation types (as identified in existing vegetation mapping) can occur within areas identified as not successional to forests in PVG mapping.

### Vegetation Communities in the Analysis Area outside Forest Service-Managed Land

As PVG mapping does not extend outside the boundaries of the PNF or BNF, LANDFIRE vegetation mapping was used to describe vegetation outside Forest Service-administered lands. Approximately 3,046 acres (18 percent) of land in the vegetation analysis area occurs on lands not administered by the Forest Service. Acres of LANDFIRE vegetation communities (excluding developed or urban land uses) in the analysis area outside Forest Service-administered lands are presented in Table 3.10-3. Descriptions and
maps of these vegetation communities are presented in Appendix B of the SGP Vegetation Specialist Report (Forest Service 2022g).

²Vegetation community impacts analyses performed solely on non-agriculture and non-developed vegetation communities.

³Due to rounding, numbers presented in this table may not sum precisely to the total provided.
Vegetation Community Trends

On the PNF, from 1989 to 2016, an average of 178 fires occurred annually with a majority of them caused by lightning. Approximately 59 percent of the PNF was affected by fire between 1989 and 2016, consisting of a mix of both characteristic and uncharacteristic fires depending upon the historic fire regime (Forest Service 2003a, 2017f). On the BNF, from 1989 to 2016, an average of 151 fires occurred annually with a majority of them caused by lightning, over 58 percent of the planning unit land base has burned between 1989 and 2016, and even though acres burned by wildfire have been increasing over the past few decades, the amount of area burned is still well below historical levels (Forest Service 2010a, 2016h). Near the vegetation analysis area, past fires within the headwaters of the East Fork SFSR and Sugar Creek include Indian Creek Point (12,206 acres); Tamarack (2,291 acres); Bishop Creek (1,452 acres); Cascade Complex (302,530 acres); and Thunder City (9,475 acres).

The effects of fire on the landscape vary depending on weather, fuel loadings, and vegetative community type. Historically, wildfires throughout the PNF and BNF ranged from ground fires to stand-replacing fires, depending on the vegetative community. Some recent wildfires have created more homogeneous landscapes than those that typically occurred within historical fire regimes. However, some recent fires in the PNF and BNF may have been more similar to historical fires in that they burned through vegetative types that historically burned infrequently, resulting in a diversity of vegetative communities and a variety of landscape mosaics (Forest Service 2003a, 2010d). Due to the complexity of the current fire regime within the analysis area, it is difficult to predict how changes in vegetation communities at the SGP may impact future fires in the analysis area.

Additionally, various factors including altered species compositions have increased the susceptibility of some plant communities to large-scale infestations of insects and pathogens, which has resulted in greater numbers of standing dead or dying trees and increases the fuel loading in these areas (Forest Service 2003a).

Gradual changes in the distribution and abundance of dominant plant species and short-term impacts on vegetation structure and age classes are expected as a result of rising temperatures and longer and more frequent droughts associated with climate change (Halofsky et al. 2017).

Surface soils in the SGP area are influenced by trace metals as a byproduct of legacy mine operations, with concentrations of antimony, arsenic, mercury, and silver in soils adjacent to the SGP being greater than screening level phytotoxicity criteria (Tetra Tech 2021a). Total arsenic was identified as having the greatest potential to cause phytotoxicity in plants growing at or near the SGP. However, soil analysis and visual observations of plant growth in reclaimed historic mine sites adjacent to the SGP suggest that plants in the area can withstand higher concentrations of trace metals than are commonly accepted as upper limits for supporting vegetation (Tetra Tech 2021a).

Desired Conditions for Vegetation

- Generalized desired conditions relating to vegetation communities in the Payette Forest Plan and Boise Forest Plan are described below. More specific desired conditions for the different components of vegetation are found in Appendix A of the Forest Plans.
Both Forest Plans: Forested vegetation reflects a combination of successional development, disturbance regimes, and management activities. Forested lands exhibit variable patterns of size classes, densities, structural stages, and species composition. Seral tree species such as ponderosa pine, Douglas-fir, aspen, and whitebark pine have increasing species composition in areas where fire and mechanical vegetation treatments are the primary tools. Snags and coarse woody debris are present in sufficient quantities to provide for habitat diversity and long-term soil productivity.

Grasslands and shrublands exhibit variable patterns of multiple-aged shrubs, grasses, and forbs. Shrublands are found in mosaics of canopy closures across the landscape, reflecting a combination of successional development, disturbance regimes and management activities. Some mid- to high-elevation grasslands are primarily meadow complexes that are dominated by sedges, rushes, grasses, and forbs.

Payette Forest Plan only: Where vegetation development is dominated by plant succession, climax species composition is increasing, canopy cover densities are moderate to high, and late successional structure develops.

Boise Forest Plan only: In areas where vegetation development evolves primarily as a result of plant succession rather than disturbance, late-seral/climax species composition and moderate to high canopy densities will increase.

### 3.10.4.2 Botanical Resources

The terms botanical resources or special status plants are generally used to denote species that are considered sufficiently rare that they require special consideration and/or protection by the federal and/or state governments. For the purposes of this section, botanical resources or special status plant species are those that are:

- Listed as threatened or endangered under the ESA, as amended (16 USC 35 Section 1531 et seq. 1988);
- Identified as candidate or proposed for ESA listing;
- Designated as sensitive on the Regional Foresters list; and/or
- Identified as forest watch plant species in the Payette Forest Plan (Forest Service 2003a) and/or Boise Forest Plan (Forest Service 2010a).

Sensitive species are defined in FSM 2670 as “plant and animal species identified by a regional forester for which population viability is a concern, as evidenced by: 1) Significant current or predicted downward trends in population numbers or density and 2) Significant current or predicted downward trends in habitat capability that would reduce a species' existing distribution.”

Forest watch species are those that are confirmed to occur in the planning area for a Forest and are listed as S1, S2, or S3 (Table 3.10-4) at the state level and are not on the Forest Service regional sensitive species list. Impacts to forest watch species are addressed in adherence to Forest Service Guideline MIOB08 (Forest Service 2003a, 2010a).
Potential habitat modeling for special status plants in the analysis area was completed to supplement existing species location information. Potential habitat was modeled for whitebark pine and 29 additional Sensitive or Forest Watch species in the PNF and BNF; modeling protocols and results are documented in the SGP EIS Technical Report: Special Status Plant Potential Habitat Modeling Report (AECOM 2020e) and were updated in 2022 (Stantec 2022).

**Endangered Species Act Threatened, Endangered, Candidate, and Proposed Species**

There are no federally threatened, endangered, or candidate plant species documented or suspected in proximity to the analysis area. The whitebark pine (*Pinus albicaulis*) is a federally proposed-threatened species known to occur in the analysis area and is discussed further below.

**Whitebark Pine**

The whitebark pine is a federally proposed-threatened species to be listed as threatened without proposed or designated Critical Habitat. On December 2, 2020, the USFWS published a proposed rule (85 FR 77408) to list the whitebark pine as a threatened species under the ESA of 1973, as amended (16 USC 1531 et seq.). Included in the proposed rule is a special rule pursuant to section 4(d) of the ESA that identifies actions necessary to conserve and recover the whitebark pine, as well as a limited number of prohibited acts (85 FR 77408). While the 4(d) rule does not relieve federal agencies of their obligations under section 7 of the Act, it includes exceptions that allow for optimal, flexible, and adaptive forest activities that can advance whitebark pine conservation.

This species is found in the analysis area (HDR 2017g; Tetra Tech 2020b; USFWS 2019a). Whitebark pine is a five-needled coniferous tree typically found in cold, windy, high-elevation or high-latitude sites in western North America, usually on steep slopes at alpine tree lines and in subalpine areas (Arno and Hoff 1989; BLM 2016; USFWS 2021). In moist mountain ranges, whitebark pine is most abundant on warm, dry exposures; but in semiarid ranges, it becomes prevalent on cool exposures and moist sites (Arno and Hoff 1989). It ranges from west-central British Columbia east to west-central Alberta and south to central Idaho, southwestern Wyoming, and southern California (NatureServe 2020a). Its distribution is split into two broad sections, one following the Coast Ranges and one following the Cascade Range, and the other following the northern Rocky Mountains, with scattered occurrences between the two sections in Great Basin regions of eastern Washington and Oregon and northern Nevada (NatureServe 2020a).

Whitebark pine is considered an important or keystone species in the ecosystems where it is found due to its function as habitat and food for wildlife, its ability to colonize areas after fire and other disturbances, its ability to survive on harsh, high-elevation droughty sites, and its function in regulating snowmelt and reducing soil erosion (Keane et al. 2017). Whitebark pine is a long-lived tree, commonly living over 400 years. Whitebark pine populations are declining in North America due to white pine blister rust disease (caused by the introduced pathogen white pine blister rust [*Cronartium ribicola]*) (85 FR 77408; Keane et al. 2017), historical and current mountain pine beetle (*Dendroctonus ponderosae*) outbreaks, and fire exclusion management policies. Climate change also is predicted to negatively affect whitebark pine as a result of warming temperatures and major shifts to disturbance regimes (Keane et al. 2017).
Special status plant surveys in which whitebark pine was among the targeted species were performed in 2012, 2013, and 2014 in portions of the analysis area (HDR 2017g). These surveys documented approximately 164 acres of whitebark pine at the SGP mine area and along Burnt Log Road (FR 447) and several existing roads, including Horse Heaven Road (FR 416w) and Meadow Creek Lookout Road (FR 51290), along the existing Old Thunder Mountain Road (FR 440), and within the transmission line corridor between Johnson Creek Road (CR 10-413) and the SGP mine area (HDR 2017g).

Forest Service botanists determined that the 2012, 2013, and 2014 whitebark pine surveys were not conducted throughout the extent of suitable habitat within the SGP footprint and data were not collected in a manner that would be useful for a comprehensive and meaningful effects analysis for this species. Therefore, Forest Service botanists requested that known habitat parameters be used to model potential habitat for whitebark pine (AECOM 2019a). Approximately 6,130 acres of potential habitat for this species was modeled along Warm Lake Road (CR 10-579), Cabin Creek Road (FR 50467), the Burntlog Route, Meadow Creek Lookout Road (FR 51290), the transmission line right-of-way, and the SGP mine area.

Surveys for whitebark pine using potential habitat modeling developed in 2019 were performed in spring, summer, and fall of 2019. The results of these surveys are reported in the 2019 Whitebark Pine Survey Report (Tetra Tech 2020b). Approximately 2,069 acres of occupied whitebark pine habitat were identified within the analysis area for vegetation resources (i.e., Tetra Tech 2020b survey data within the 300-foot buffer on either side of all action alternative components). The 300-foot buffer was selected to encompass an area where direct and indirect impacts (e.g., dust, impacts to pollinators, etc.) from the action alternatives could impact vegetation.

**Sensitive and forest Watch Species**

Species Known to Occur in the Analysis Area

Two plant species designated as sensitive by the Forest Service are known to occur within or immediately adjacent to the analysis area. These species are least moonwort (*Botrychium simplex*) and Sacajawea’s bitterroot (*Lewisia sacajaweana*). Four forest watch species are known to occur within or immediately adjacent to the analysis area. These are bent-flowered milkvetch (*Astragalus vexilliflexus* var. *vexilliflexus*), Blandow’s helodium (*Helodium blandowii*), sweetgrass (*Hierochloe odorata*), and Rannoch-rush (*Scheuchzeria palustris*).

The state and global conservation status rank for each of these plants and Forest Service status as either a sensitive or forest watch species is presented in **Table 3.10-4**. State and global conservation status ranks are categorizations of the relative imperilment and rarity of a species at the state or global level (NatureServe 2012). Conservation status ranks do not have any regulatory authority but are useful in understanding the overall degree of vulnerability of a species to impacts that could occur from the SGP. More information for each of these species is presented below.

Source: AECOM 2020e; Forest Service statuses and state ranks are from rare plant lists for the PNF (Forest Service no date) and BNF (Forest Service 2015a). Global ranks are from NatureServe Explorer database (NatureServe 2020b).

1State ranks are from rare plant lists for the PNF (Forest Service no date) and BNF (Forest Service 2015a). State ranks for species not on rare plant lists for the PNF or BNF and global ranks for all species are from NatureServe Explorer database (NatureServe 2020b).

S = State rank indicator; denotes rank based on status within Idaho.

G = Ranks designated at the global (or range-wide) level.

T = Infraspecific taxa (subspecies, plant varieties, and other designations below the level of the species) rank indicator, appended to the global rank for the including species.

1 = Critically imperiled — Typically having 5 or fewer occurrences, or 1,000 or fewer individuals.

2 = Imperiled — Typically having 6 to 20 occurrences, or 1,001 to 3,000 individuals.

3 = Vulnerable — Rare; typically having 21 to 100 occurrences, or 3,001 to 10,000 individuals.

4 = Apparently secure — Uncommon but not rare, but with some cause for long-term concern; typically having 101 or more occurrences, or 10,001 or more individuals.

5 = Secure — Common, widespread, abundant, and lacking major threats or long-term concerns.

2This column references a species’ status as sensitive on the Forest Service Region 4 (Intermountain Region) Proposed, Endangered, Threatened, and Sensitive Species List (Forest Service 2016c), regardless of whether this species is indicated on this list as being present in either the PNF or BNF.

3This column states if species is designated as sensitive or as a forest watch species according to the PNF rare plant list (Forest Service no date). *Botrychium simplex* is considered a sensitive plant species in the PNF even though the PNF rare plant list indicates it as a forest watch species (Forest Service 2020c).

4This column states if a species is designated as sensitive or as a forest watch species according to the BNF rare plant list (Forest Service 2015a). *Botrychium simplex* is considered a forest watch species in the BNF even though it is a sensitive species at the Region 4 level (Forest Service 2020d).

R4 = Species is designated as sensitive for the Forest Service Region 4 (Intermountain Region).

**Bent-flowered Milkvetch**

Bent-flowered milkvetch occurs over a range that extends from southern British Columbia and Alberta to southwestern Montana, western Wyoming, and Idaho, eastward to Saskatchewan and South Dakota (Mancuso 2016) (CPNWH 2018). Idaho populations occur on exposed, subalpine ridgelines in subalpine fir and whitebark pine parklands on subalpine ridges and upper slopes and all aspects (Mancuso 2016) from 7,500 to 8,500 feet (Forest Service no date). Vegetation in areas of known locations is very open with low ground cover (Mancuso 2016; Moseley 1994). The three occurrences of this species in Idaho all occur in the PNF planning area (Mancuso 2016).
Five subpopulations of a single occurrence (the Cinnabar Peak occurrence) of this species were
documented during surveys in 2012, 2013 (HDR 2017g), and 2016 (Mancuso 2016, IFWIS 2017). The
nearest subpopulation of the Cinnabar Peak occurrence extends from about 300 feet to one-quarter mile
upslope from and to the east of the West End Creek diversion. This subpopulation, which consists of an
estimated total of 7,000 to 10,000 plants, is about 25 acres in size and is located in a relatively
undisturbed area. This subpopulation is the largest contiguous area of occupied habitat for this species in
Idaho and is considered to be critical to the long-term viability of this species, as it could serve as seed
sources for future conservation efforts. The other subpopulations of this occurrence and the other
occurrences of this species are located outside the analysis area for the SGP. These subpopulations and
occurrences are all smaller in extent and population size than the Cinnabar Peak subpopulation of the
Cinnabar Peak occurrence (Mancuso 2016).

**Least Moonwort**

Least moonwort occurs throughout the Rocky Mountain Range in British Columbia, Alberta,
Washington, Oregon, Idaho, Montana, and Wyoming; Cascade Range in Washington, Oregon, and
California; and Sierra Nevada Range in California (CPNWH 2018). Least moonwort is found in a variety
of habitats including meadows, forests, and roadside areas (Colorado Natural Heritage Program 2006;
Forest Service 2015a, no date), dry fields, marshes, bogs, swamps, and roadside ditches, usually in areas
with subacid soils (NatureServe 2020c).

Two subpopulations of a single occurrence of least moonwort occur in swales adjacent to Johnson Creek
Road. However, these subpopulations were last observed in 2004 and had estimated population sizes of
approximately 360 plants in each subpopulation (IFWIS 2017) but were not observed by Forest Service
surveyors in the most recent survey year (2005) (IFWIS 2017). This species was not included in past
SGP-related surveys in 2012, 2013, or 2014 (HDR 2017g).

**Blandow’s Helodium**

Blandow’s helodium occurs in the Rocky Mountain, Cascade, Alaska, and Brooks ranges in Alaska, and
in the provinces of Yukon, British Columbia, and Alberta in Canada and in Washington, Oregon,
Montana, Idaho, and Wyoming (CPNWH 2018). Habitat for this species is mats and hummocks in
montane peatlands, fens, and bogs, and under sedges and shrubs or along streams in mires (Forest Service
2015a). It occurs in wetlands and along streams between 3,900 to 6,600 feet elevation in and at edges of
conifer forests on the eastside of the PNF (Forest Service no date). It forms in mats and small hummocks
in medium to rich montane fens with calcareous groundwater and sometimes occurs under sedges and
shrubs around the edges of fens or along streamlets in fens (Forest Service 2007b).

A single occurrence of Blandow’s helodium occurs in the analysis area near Trapper Creek approximately
100 feet from where the Burntlog Route would cross the Trapper Flat wetland (IFWIS 2017). This
occurrence was last observed in 2004 and consists of an unknown number of individuals (IFWIS 2017)
and was not included in past SGP-related surveys in 2012, 2013, or 2014 (HDR 2017g).
**Sweetgrass**

The range for sweetgrass is the Rocky Mountain, Cascade, Alaska, and Brooks ranges in Alaska (including Seward Peninsula), the provinces of Yukon, British Columbia, and Alberta in Canada, and the states of Washington, Oregon, Montana, Idaho, Wyoming, and Utah (CPNWH 2018). Its habitat is described as moist slopes, meadows, and streambanks from the foothills to subalpine elevations (Forest Service 2015a), moist soil of lower montane to subalpine meadows and slopes (Hitchcock and Cronquist 1973), and edges of sloughs and marshes, bogs, shaded streambanks, lakeshores, and cool mountain canyons (Walsh 1994).

A single occurrence of sweetgrass is found in the analysis area in the wetlands near Trapper Creek, approximately 780 feet to over 1,000 feet from where the proposed Burntlog Route would cross the Trapper Flat wetland area (IFWIS 2017). The location of this species is hydrologically connected to the proposed location of the proposed new road through the wetlands around Trapper Creek under the 2021 MMP and is thus considered to be within the analysis area. This occurrence was last observed in 2004 and consists of an unknown number of individuals (IFWIS 2017). This species was not included in past SGP-related surveys in 2012, 2013, or 2014 (HDR 2017g).

**Sacajawea’s Bitterroot**

The range for Sacajawea’s bitterroot is the Rocky Mountains in Idaho (CPNWH 2018), with roughly three-fourths of the populations occurring on the BNF (Forest Service 2014a).

Sacajawea’s bitterroot inhabits relatively sparsely vegetated upper slopes and ridgetops in montane and subalpine habitats on the PNF and some areas of the BNF (Forest Service 2015a; NatureServe 2020d) in areas with fractured bedrock and granitic soils near late snowbanks at elevations of between 5,400 to 9,500 feet (Forest Service 2015a). Vegetation communities around existing populations are mostly bare subalpine woodlands and open ridges, but it also is known to occur in Ponderosa pine habitat on the BNF from 4,500 to 6,500 feet (Forest Service no date).

A single occurrence of Sacajawea’s bitterroot occurs in the analysis area approximately 300 feet above Warm Lake Road and the existing transmission line corridor near the intersection of Warm Lake Road and Curtis Creek Road. This occurrence was last observed in 1999 and has an unknown number of individuals (IFWIS 2017). This occurrence was not documented by surveyors in 2014 although this species was targeted during surveys that year (HDR 2017g).

**Rannoch-rush**

The range for Rannoch-rush is from the Rocky Mountain, Alaska, and Cascade ranges in Alaska, the Canadian provinces of Yukon and British Columbia, and the states of Washington, Oregon, Idaho, and Montana (CPNWH 2018). Its habitat is full sun areas in sphagnum bogs and peatlands (NatureServe 2020e) (Forest Service 2015a).
A single occurrence of this species has been documented in the analysis area by the IDFG in the Mud Lake area (IDFG 2004; IFWIS 2017) approximately 200 feet from an existing portion of Burnt Log Road (FR 447). This occurrence was last observed in 2001 and has an unknown number of individuals (IFWIS 2017). This species was not included in past SGP-related surveys in 2012, 2013, or 2014 (HDR 2017g).

**Species with the Potential to Occur in the Analysis Area**

Modeled potential habitat (as well as mapped occupied habitat for the whitebark pine) for Forest Service-designated sensitive or forest watch species occurs on 19,492.4 acres in the analysis area, all within the boundaries of the PNF and BNF. Areas of modeled potential habitat occur on approximately 38 percent of the analysis area or 60 percent, and 2 percent of lands administered by the PNF, BNF, and Salmon-Challis NF, respectively.

**Table 3.10-5** presents a list of the 29 sensitive or forest watch species that have the potential to occur in the analysis area and for which habitat modeling was performed. Modeling methods, results, and rationale for determining that these species have potential to occur in the analysis area are presented in the SGP EIS Technical Report: Special Status Plant Potential Habitat Modeling Report (AECOM 2020e) and updated in 2022 (Stantec 2022). This table also presents information on whether past surveys have been completed for these species, any populations within or near the analysis area, and the extent and general area of modeled potential habitat for these species within the analysis area.

</table>

Source: Perpetua 2021a; Refer to AECOM 2020e and Stantec 2022 for rationale used in determining presence or absence of potential habitat for species in the analysis area.

1State ranks are from rare plant lists for the PNF (Forest Service no date) and BNF (Forest Service 2015a). State ranks for species not on rare plant lists for the PNF or BNF and global ranks for all species are from NatureServe Explorer database (NatureServe 2020b).

S = State rank indicator; denotes rank based on status within Idaho.; G = Ranks designated at the global (or range-wide) level.; T = Infraspecific taxa (subspecies, plant varieties, and other designations below the level of the species) rank indicator, appended to the global rank for the including species. 1 = Critically imperiled — Typically having 5 or fewer occurrences, or 1,000 or fewer individuals. 2 = Imperiled — Typically having 6 to 20 occurrences, or 1,001 to 3,000 individuals. 3 = Vulnerable — Rare; typically having 21 to 100 occurrences, or 3,001 to 10,000 individuals. 4 = Apparently secure — Uncommon but not rare, but with some cause for long-term concern; typically having 101 or more occurrences, or 10,001 or more individuals.

5 = Secure — Common, widespread, abundant, and lacking major threats or long-term concerns.
H = Historical occurrence (i.e., formerly part of the native biota; implied expectation that it might be rediscovered or possibly extinct).
NR = Not ranked.
2This column references a species’ status as sensitive on the Forest Service Region 4 (Intermountain Region) Proposed, Endangered, Threatened, and Sensitive Species List (Forest Service 2016c), regardless of whether this species is indicated on this list as being present in either the PNF or BNF.
3This column states if species is designated as sensitive or as a forest watch species according to the PNF rare plant list (Forest Service no date). Least moonwort (*Botrychium simplex*) is considered a sensitive plant species in the PNF even though the PNF rare plant list indicates it is a forest watch species (Forest Service 2020c).
4This column states if a species is designated as sensitive or as a forest watch species according to the BNF rare plant list (Forest Service 2015a). Scalloped moonwort (*Botrychium crenulatum*), least moonwort (*B. simplex*), and short-style tofieldia (*Triantha occidentalis* ssp. *brevistyla*) are considered forest watch species in the BNF even though they are designated as sensitive at the Region 4 level (Forest Service 2020d).
5Occurrence data for species were derived from IFWIS spatial data (IFWIS 2017).
6Refers to past SGP-related surveys performed by contractors for Midas Gold in 2012, 2013, and 2014 (HDR 2017g).
7Figures showing the modeled potential habitat for these species can be found in Appendix E of the Vegetation Specialist Report (Forest Service 2022g).
8Beautiful bryum (*Bryum calobryoides*) is ranked as a state historical species but was included in this analysis as a sensitive species in the BNF and its habitat conditions match those found in portions of the analysis area.
R4 = Species is designated as sensitive for the Forest Service Region 4 (Intermountain Region).
3.10.4.3 Non-Native Plants

Non-native plants are those that have been introduced by humans into an area where they are not native and that are able to establish on many sites, grow quickly, and spread to the point of disrupting plant communities or ecosystems, or whose introduction causes or is likely to cause economic or environmental harm or harm to human health (EO 13112). Noxious weeds are non-native plants designated by the Director of the Idaho State Department of Agriculture (ISDA) as having the potential to cause injury to public health, crops, livestock, land, or other property (Idaho Statute 22-2402). The ISDA is responsible for administering the State Noxious Weed Law in Idaho and maintains a list of noxious species. Noxious weeds are managed by the Forest Service on NFS lands with cooperation from ISDA and Tribal and County governments. Noxious weed categories are as follows:

- **Early Detection and Rapid Response** – Plants in this category must be reported to the ISDA within 10 days of being identified by an approved, qualified authority. Eradication must begin in the same season the species is found. No known species of Early Detection and Rapid Response are known in the subregion.

- **Containment** – The goal for these species is to reduce or eliminate new or small infestations and to manage established populations as determined by the weed control authority.

- **Control** – The goal for these species is to reduce or eliminate new or expanding weed populations. In some areas of the state, control or eradication is possible, and a plan must be written that will reduce infestations within 5 years.

Table 3.10-6 lists the noxious weeds and non-native plant species documented in the analysis area and surrounding area in Valley County, Idaho. Species in this table that have or have not been documented in the analysis area have the potential to spread from surrounding areas throughout the analysis area. Noxious weeds and non-native plants are commonly found along roads and in other areas disturbed by soil movement or vegetation clearing. Locations of non-native plant invasions as recorded by the Forest Service and Perpetua contractors (HDR 2017g) in the analysis area are shown in Appendix C of the SGP Vegetation Specialist Report (Forest Service 2022g). Spotted knapweed (Centaurea stoebe ssp. micranthos) and rush skeletonweed (Chondrilla juncea), both Containment species, are the most extensive in the analysis area and generally occur along roads (Forest Service 2019c).

3.11  Wetlands and Riparian Resources

3.11.1  Introduction

This section describes the existing conditions of wetland and riparian resources in the analysis area. It presents an overview of general hydrologic conditions, followed by an inventory of existing wetlands, streams, open waters, and riparian areas. Wetland functions and values in the analysis area for wetlands is also described. Additional details and information can be found in the SGP Wetlands and Riparian Resources Specialist Report (Forest Services 2022h).

3.11.2  Wetlands and Riparian Resources Area of Analysis

The analysis area for wetland and riparian resource includes the area where effects (direct/indirect and cumulative) may be caused by the proposed activities (FSH.1909.15, 15.2a). The analysis area for direct/indirect effects is shown on Figure 3.11-1. It encompasses the following seven watersheds (HUC 10): Big Creek North Fork Payette River, Gold Fork River, Indian Creek, Johnson Creek, Lake Fork-North Fork Payette River, Upper East Fork SFSR, and Upper SFSR. Within these watersheds, the analysis area includes a mine site focus area and an off-site focus area, which includes off-site components of the SGP. Wetlands were not evaluated within the larger surrounding watersheds for the off-site corridors or areas not associated with the SGP.

3.11.3  Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to Wetland and Riparian Resources. Additional descriptions of these regulations can be found in the SGP Wetland and Riparian Resources Specialist Report (Forest Service 2022h).

Land and Resource Management Plan: The Payette Forest Plan and the Boise Forest Plan include management direction for wetlands and riparian areas. They include guidelines for RCAs, which are defined as “traditional riparian corridors, perennial and intermittent streams, wetlands, lakes, springs, reservoirs, and other areas where proper riparian functions and ecological processes are crucial to maintenance of the area’s water, sediment, woody debris, nutrient delivery system, and associated biotic communities and habitat.”

Aquatic resources on NFS lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. Desired conditions are descriptions of how forest resources should look and function to provide diverse and sustainable habitats, settings, goods, and services. Taken together, the desired conditions should present an integrated vision of a properly functioning forest that supports a broad range of biodiversity and social and economic opportunities.

Clean Water Act: Federal regulations governing discharges of dredged or fill material into WOTUS, including wetlands, streams, and open waters, are promulgated under Section 404 of the CWA, as administered by the USACE. Under Section 404 of the CWA; WOTUS, fall under the jurisdiction of the USACE. Thus, any discharge of dredged or fill material into jurisdictional wetlands or other WOTUS in the SGP area would require a DA Authorization.
Additionally, Section 404(b)(1) guidelines (Guidelines) promulgated by the EPA, in conjunction with the USACE, apply to an applicant’s proposed disposal site(s) for discharges of dredged or fill material into WOTUS. The Guidelines prohibit, for example, the authorization of a proposed discharge that would cause or contribute to the violation of an applicable water quality or toxic effluent standard or jeopardize a listed threatened or endangered species. The Guidelines also prohibit the authorization of a proposed discharge which will cause or contribute to significant degradation of the aquatic ecosystem. Findings of significant degradation must be based upon specific factual determinations, evaluations, and tests identified in the Guidelines. These include the evaluation of direct, indirect, and cumulative effects of the proposed discharge and alternatives on specific resources including fish, wildlife, and special aquatic sites.

These Guidelines state that no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge that would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. The Guidelines also state that no discharge of dredged or fill material is permitted unless appropriate and practicable steps have been taken to minimize potential adverse effects to the aquatic ecosystem. Subpart H of the Guidelines identifies many possible steps to avoid, minimize, and compensate for direct and secondary adverse impacts. Taken together, these steps form the mitigation sequence: a mandatory, sequential process undertaken to “minimize potential adverse impacts of the discharge on the aquatic ecosystem.” Demonstrating compliance with the Guidelines requires identifying the appropriate and practicable steps that will be taken to avoid impacts, and then minimize and compensate for any remaining unavoidable impacts associated with discharges subject to the Guidelines.

For unavoidable impacts to wetlands, streams, and other WOTUS, the 404(b)(1) Guidelines require appropriate and practicable compensatory mitigation to offset unavoidable impacts. In 2008, the USACE and the EPA issued a final rule for Compensatory Mitigation for Losses of Aquatic Resources. This final rule contains the regulations that govern compensatory mitigation for activities that require a permit from the USACE (USACE and EPA 2008). Compensatory mitigation is defined as the restoration, establishment, enhancement, and/or in certain circumstances preservation of aquatic resources for the purposes of offsetting unavoidable adverse impacts that remain after all appropriate and practicable avoidance and minimization has been achieved.

Section 402 of the CWA, which authorizes the NPDES permit program, controls water pollution by regulating point sources that discharge pollutants other than dredged and fill material into WOTUS. On June 5, 2018, EPA approved the IPDES Program and authorized the transfer of permitting authority to the state beginning on July 1, 2018.

Executive Order 11990: EO 11990 requires that federal agencies, to the extent permitted by law, shall avoid undertaking or providing assistance for new construction located in wetlands, unless the head of the federal agency trying to work in wetlands finds that: 1) no practicable alternative to such construction exists; and 2) the project would include all practicable measures to minimize harm to wetlands that may result from such use (42 Federal Register 26961, 3 CFR 1977 Comp, p. 121).
State Regulations: Projects that may result in a discharge to WOTUS require Water Quality Certification under Section 401 of the CWA. Section 401 gives the authority to issue this certification, ensuring that the discharge complies with state water quality standards. The IDEQ is the regulatory authority for Section 401 permitting in Idaho. IDEQ must grant (with or without conditions), deny, or waive Section 401 certification for any project in Idaho that requires a federal permit or license under the CWA before the federal permit or license can be issued. This Water Quality Certification is made to ensure that a proposed project would comply with state water quality standards for surface water and any other water quality requirements under state law.

The IDWR regulates stream channels under the Idaho Stream Channel Protection Act. This act requires that a Stream Channel Alteration Permit be obtained from the IDWR before any type of alteration work, including removal and/or fill and installation of in-water or over-water structures with the potential to affect flow, within the beds and banks of a continuously flowing stream.

The Emergency Wetlands Resources Act of 1986 requires that states develop prioritized lists of wetlands that meet the criteria of 1) supporting rare or declining wetland types; 2) having identifiable threats of loss or degradation of wetland functions; and 3) having diverse and important functions and values (including recreation), or especially high value for specific functions. To meet the requirements of the Emergency Wetlands Resources Act, IDFG maintains a Wetland Conservation Prioritization Plan (IDFG 2012) and a list of wetland sites in need of acquisition for long-term conservation and management.

Valley County Regulations: Valley County reviews development proposals for consistency with the County’s Land Use Development Ordinance. When permits are required by other agencies for all or parts of the application, evidence of the permit and compliance with the provisions of the permit are to be a condition of the land use approval. This includes permits to alter wetlands, permits to construct in flood prone areas, and in other situations where the review and issuance of the permit would assure the Valley County Commission that the proposal would be technically feasible.

3.11.4 Affected Environment

3.11.4.1 General Hydrologic Landscape Setting

Operations Area Boundary

The main drainage basin in the Operations Area Boundary is the East Fork SFSR watershed (HUC 1706020802). The East Fork SFSR is joined by Johnson Creek near the village of Yellow Pine, downstream of the mine site. The SGP would be in several drainages that are all tributaries to the East Fork SFSR, including Meadow Creek, EFMC (also known as Blowout Creek), Garnet Creek, Fiddle Creek, Hennessy Creek, Midnight Creek, West End Creek, and Sugar Creek. Wetlands located on slopes and tributary drainages within and near the mine site area are associated with hillside seeps and springs (HydroGeo 2012b). In most cases, these seep and spring features are hydrologically connected to a larger wetland/stream complex in the valley floor and/or a stream downslope via surface flow (HDR 2017h). Snowmelt runoff and groundwater inputs also contribute to the hydrologic support of wetlands at the mine site.
As a result of almost a century of mining and exploration in the mine site area, numerous wetlands and streams have been altered, particularly those adjacent to former mine pits, tailing storage areas, and roads (Forest Service 1994). Previous mine operators excavated and/or filled wetlands to construct mineral processing facilities, development rock storage facilities, tailing storage facilities, mine access and haul roads, town sites, and other mining-related developments. Most of these activities occurred before enactment of the CWA in 1972 and associated mitigation requirements. Within the mine site focus area approximately 847 acres have been modified by past human activity and are considered highly disturbed. This area represents approximately 49 percent of the proposed disturbance for the SGP mine site area. The history of excavation and mine tailings storage at the mine site has introduced areas of soil contamination, which are often in, or adjacent to, wetlands and riparian areas (Midas Gold 2016a). Soils in areas where vegetation is removed or disturbed are more susceptible to wind and water erosion (Forest Service 1994). As such, in disturbed areas the water quality and soil stabilizing properties of intact wetlands and riparian areas make them especially important in maintaining and improving watershed conditions.

3.11.4.2 Off-Site Focus Area

SGP features in the off-site focus area portion of the analysis area would cross several watersheds: Upper East Fork SFSR (HUC 1706020802), Johnson Creek (HUC 1706020801), Upper SFSR (HUC 1706020804), Gold Fork River (HUC 1705012303), Big Creek North Fork Payette River (HUC 1705012305), Lake Fork-North Fork Payette River (HUC 1705012302), and Cascade Reservoir (HUC 1705012304). The Johnson Creek watershed drains to Johnson Creek, which flows northward. The Upper SFSR watershed drains to the SFSR, which flows northward. The Gold Fork River, Big Creek North Fork Payette River, Lake Fork-North Fork Payette River, and Cascade Reservoir watersheds all drain toward Cascade Lake and the North Fork Payette River.

The off-site focus area includes proposed access roads that would leave the mine site and travel west along East Fork SFSR, southwest along Burntlog Creek, and south along Johnson Creek towards Landmark. In these areas, wetlands along the roads include hillside seeps on slopes and valley-bottom riparian wetlands in narrow valleys (Forest Service 2010a).

The transmission line corridor would pass along hill tops located between the mine site and Johnson Creek Road (CR 10-413). The few wetlands in this area are generally limited to wetland seeps that act as the headwaters for ephemeral and intermittent streams. From the vicinity of Landmark, an existing transmission line continues west, crossing over hills and across stream valleys in the vicinity of Warm Lake. Approaching the City of Cascade, the general topography transitions from the Long Valley foothills down to the broad, Long Valley basin around Cascade Reservoir at 4,800 feet elevation. At this western end of the off-site focus area, the main geomorphic landforms are depositional plains with slope gradients averaging between 0 to 20 percent (Forest Service 2010a). Large, wide arrays of wetland and riparian habitat are located along the bottomlands surrounding the Cascade Reservoir (Forest Service 2010a). In many locations, aquatic habitats have been affected by roads, livestock grazing, timber harvest, and recreational use (Forest Service 2010a). Historical impacts include streambank erosion, degradation, rapid deposition of eroded sediments, and stream channel modification (Forest Service 2010a). Aquatic habitat is not functioning properly in some locations within the off-site focus area due to habitat fragmentation from roads and timber harvest, high sediment levels, and impacts to riparian areas (Forest Service 2010a).
3.11.4.3 Wetlands

Wetlands were identified and delineated using the methods described in Corps of Engineers Wetlands Delineation Manual (Corps Manual) (Environmental Laboratory 1987) and the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys and Coast Region (Environmental Laboratory 2010; HDR 2017h). According to the Corps Manual, identification of wetlands is based on a three-factor approach involving indicators of hydrophytic vegetation, hydric soil, and wetland hydrology (Environmental Laboratory 1987). Wetlands were further classified and described by their vegetation structure per the Classification of Wetlands and Deepwater Habitats (Cowardin et al. 1979) or as “Open Water.”

Table 3.11-1 provides a summary of the wetlands delineated within portions of the Mine Site and Off-site Focus Areas of the larger wetland analysis area broken out by Cowardin Classification as further described in the Wetland and Riparian Areas Specialist Report (Forest Service 2022h). See Section 3.10 Vegetation, for additional discussion of wetland vegetation characteristics in the analysis area, Section 3.5 for additional discussion of hydric soil conditions in the analysis area: and Sections 3.8 and 3.9 for additional information on surface water hydrology. Wetlands provide important ecological functions for associated streams and rivers. For example, they may protect fish by providing habitat during high flows, or they may remove nutrients and toxicants from waters to improve water quality in streams and rivers.

</tr>
</tbody>
</table>

Any apparent discrepancies between totals are due to rounding of numbers.

Palustrine Emergent Wetland

The PEM wetland community is often present in large sedge meadows or associated with hillside seeps. Vegetation primarily consists of various grasses, sedges, moss, and forbs, such as swordfern rush (*Juncus ensifolius*), beaked sedge (*Carex rostrata*), Nebraska sedge (*Carex nebrascensis*), angelica (*Angelica arguta*), cow parsnip (*Heracleum lanatum*), Fendler’s meadow-rue (*Thalictrum fendleri*), horsetail (*Equisetum fluviatile* and *E. hyemale*), and monkeyflower (*Mimulus lewisii* and *M. guttatus*).

Palustrine Scrub-Shrub Wetland

The PSS wetland community commonly includes alder (*Alnus* spp.), willow (*Salix* spp.), bog birch (*Betula glandulosa*), and currant (*Ribes* spp.) in the shrub stratum, with an herbaceous understory consisting of grasses, sedges, and forbs such as swordfern rush, beaked sedge, horsetails, and monkeyflowers. A thick moss mat is common in the wettest scrub-shrub communities.
**Palustrine Forested Wetlands**

The PFO wetland community commonly includes Engelmann spruce (*Picea engelmannii*), subalpine fir (*Abies lasiocarpa*), and lodgepole pine (*Pinus contorta*) in the tree stratum (i.e., layer); alder, willows (*Salix boothii* and *S. drummondiana*), and currant in the shrub stratum; and various wetland forbs and grasses in the herb stratum.

**Fens**

Fens are permanently saturated PSS or PEM wetlands that form where a thick layer of partially decomposed organic matter, called peat, accumulates under water-soaked conditions (at least 8 to 16 inches within the upper 31.5 inches of the soil profile). Fens receive a significant portion of their hydrologic input and nutrients from water that has percolated through mineral soil and bedrock, and because of their unique characteristics, they tend to support a diverse plant and wildlife community. Fens range from poor fens, which are acidic (pH 4.0 to 5.5) and support more bog-type species (e.g., sphagnum moss), to rich fens, which are less acidic and are dominated by sedges, other graminoids, and true mosses (IDFG 2005a).

The wetland delineation and functional assessment surveys and reports prepared by HDR between 2011 and 2016 and amended by Tetra Tech in 2018 did not refer to any documented wetlands specifically as fens within areas surveyed. In 2017, Midas Gold reassessed the initial data collected by wetland delineators (HDR 2013, 2014a, 2014b, 2015a, 2016b, 2016c) for the presence of fens and determined that the wetland datasheets did not indicate the presence of fens (Midas Gold 2017f). However, based on the indication of peat in soils at the TSF dam location and the adjacent TSF Buttress in geotechnical reports prepared for the SGP (SRK 2012; STRATA 2014a, 2014b, 2016, 2017; Tierra Group 2018), the Forest Service and USACE requested that Midas Gold reassess the sample plot datasheets from the wetland delineation surveys to determine if any wetlands encountered during those surveys had fen characteristics (e.g., appropriate geomorphic location, organic soils, prolonged near-surface water table, and associated plant species), and that Midas Gold provide a report to document the methods, data reviewed, and results of their reassessment. Midas Gold’s contractor (Tetra Tech) reviewed datasheets in the vicinity of the TSF and the adjacent TSF Buttress and determined that wetlands in these areas did not meet the characteristics of fens (Tetra Tech 2019b). Wetland delineation datasheets for other SGP component areas were not reassessed for the presence of potential fens as part of the Tetra Tech (2019) review.

IDFG considers wetlands associated with Mud Lake, Tule Lake, and Warm Lake, to be poor fens (IDFG 2004). Mud Lake and its associated wetlands are designated as a Class I site under the Wetland Conservation Prioritization Plan (IDFG 2012), indicating that this area is in near pristine condition and likely provides habitat for high concentrations of state rare plant or animal species (IDFG 2004). All these sites are within the analysis area for wetlands and riparian resources but outside of the construction footprint for the SGP. Mud Lake occurs near the existing Burnt Log Road (FR 447) and Warm Lake and Tule Lake occur south of Warm Lake Road (CR 10-579). For this analysis, wetlands associated with Mud Lake, Tule Lake, and Warm Lake are considered fens.
3.11.4.4 Streams and Riparian Areas

Riparian corridors are areas with distinctive soil and vegetation between a stream or other body of water and an adjacent upland, where elements of both aquatic and terrestrial ecosystems mutually influence each other (Forest Service 2003a; Knutson and Naef 1997). Riparian areas often overlap with wetlands and the portions of floodplains and valley bottoms that support riparian vegetation. Vegetated riparian buffers trap sediment, shade stream corridors, provide migratory corridors for wildlife, contribute woody debris and litter to streams, improve water quality by intercepting runoff from adjacent uplands, provide important habitat for terrestrial and avian species, and stabilize streambanks to prevent erosion.

RCAs are delineated along perennial and intermittent streams, and are determined either in the field, based on professional judgement of ecological function and process or, in the absence of field data, as follows (Forest Service 2003a):

- For forested streams (perennial), the RCA is defined as the land within a buffer of 300-feet slope distance from the ordinary high-water mark. This includes intermittent streams providing seasonal rearing and spawning habitat (Forest Service 2003a).
- For forested streams (intermittent), the RCA is defined as the land within a buffer of 150-feet slope distance from the ordinary high-water mark.
- For non-forested streams (perennial and intermittent), the RCA is defined as the land within a buffer equal to the extent of the flood prone width, or riparian vegetation, whichever is greatest.

Perennial and intermittent streams that support riparian and/or wetland vegetation along their streambanks occur throughout the analysis area. RCAs within the Mine Site and Off-site Focus Areas associated with perennial and intermittent streams mapped within the analysis area are presented in Table 3.11-2. The major drainages in the analysis area are described in Table 3.11-3. Note that since many riparian areas may also include delineated wetlands, there is overlap in the acreages of RCAs listed in Table 3.11-2 and wetlands listed in Table 3.11-3. General descriptions of riparian habitats taken from the primary drainages documented in available stream evaluations for the SGP (HDR 2016b; Rio Applied Science and Engineering 2019) are presented below. The most common riparian vegetation species that have been observed surrounding drainages in the analysis area include alder, willow, currant, and red-osier dogwood (*Cornus sericea*), with an understory of various forbs and grasses, particularly in open areas not otherwise dominated by shrubs (Forest Service 1994; HDR 2013). Portions of streams in the mine site focus area, and their associated riparian areas, have been affected by legacy mining-related activities (Forest Service 1994).

### Table 3.11-2 Streams and RCAs in the Analysis Area

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Meadow Creek</td>
<td>Mine Site</td>
<td>Presence-BT, CS Critical Habitat-BT, CS</td>
<td>Meadow Creek is a major tributary to the East Fork SFSR that flows through a flat-bottomed valley surrounded by steep mountains. Elevations range from approximately 6,200 feet above sea level in the lower reach to over 7,500 feet in the headwaters. Meadow Creek has been heavily impacted by legacy mining-related activities, including deposition of tailings and spent heap leach ore, ore processing facilities, heap leach pads, and other infrastructure, stream relocation into a straightened riprap channel, and construction of an airstrip (Midas Gold 2016a). The downstream end of the valley shows remnant effects from early mining activities, along with a large outwash feature created by a dam failure in the EFMC drainage south of the site of the Meadow Creek Mine. Portions of the creek have been modified over the years to improve conditions caused by past mine operations, including the regrading and revegetation of the 2 percent gradient lower reach of the creek in 2004 and 2005. The middle reach of Meadow Creek is an engineered channel that was constructed to bypass the spent ore disposal area. The channel was lined with riprap over geotextile fabric and is confined between reinforced/engineered slopes with a gradient of less than 2 percent. This reach has a short section with a 9 percent gradient, shallow depths, and few pools, which may be a partial fish migration barrier at low flows. The channel includes low-gradient riffles, glides (section of the stream coming out of a pool) and runs. There is no side channel development or potential large woody debris recruitment. The upper reach of Meadow Creek encompasses the headwaters downstream to the location of the proposed TSF Buttress. Upper Meadow Creek is confined and high gradient at the most upstream extent and low gradient and unconfined immediately upstream of the spent ore disposal area in lower Meadow Creek, transitioning from a gradient of 4 to 8 percent to 2 to 4 percent. Habitat is composed of riffles, step runs (sequence of runs separated by shorter riffle steps), and pools. The presence of side channels in some portions provide potential for lateral channel movement in the less confined sections. Immediately upstream of the spent ore disposal area, Meadow Creek is unconfined, with a gradient less than 1 percent. The reach is composed of low-gradient riffle, step run, and pool habitat. The floodplain is active with oxbow cutoffs, side channels, and backwater features.</td>

<td>East Fork SFSR</td>
<td>Mine Site, McCall-Stibnite Road (CR 50-412) (temporary access), Utilities</td>
<td>Presence-BT, SH, CS Critical Habitat-BT, SH, CS</td>
<td>This perennial headwater stream flows through most of the analysis area. The ordinary high-water mark (OHWM) is 2 to 3 feet deep by 25 to 30 feet wide. A human-made, open-water pond (approximately 4.5 acres) is located in the Yellow Pine pit. The steep cascade of the East Fork SFSR spilling into the pond cuts off fish passage. The stream has relatively abundant riparian vegetation, except in the vicinity of the Yellow Pine pit. Per the Payette Forest Plan, riparian vegetation in the Big Creek/Stibnite Management Area is at or near properly functioning condition, except for localized areas affected by mining, roads, and recreation.</td>
</tr>
<tr>
<td>Fiddle Creek</td>
<td>Mine Site, Access Roads</td>
<td>Presence-None known</td>
<td>Fiddle Creek is a small tributary of the East Fork SFSR just upstream of Midnight Creek. Habitat conditions in the creek have been impacted as a result of legacy mine operations, road construction, and culvert installation (Midas Gold 2016a). Fiddle Creek also was the site of a former water storage reservoir in the lower watershed, the construction and operation of which degraded portions of the stream. The lower reach of Fiddle Creek has an approximate 37 percent gradient where it flows into the East Fork SFSR, creating a complete barrier to upstream fish passage (HDR 2016b). Upstream of this barrier, Fiddle Creek retains a relatively high gradient in a relatively narrow channel, with side channels (HDR 2016b). The creek has a thick tall-shrub overstory dominated in its lower portion by gray alder (<em>Alnus incana</em>). The uppermost section of Fiddle Creek flattens in gradient, becoming a slower meandering stream due to natural glacial topography. Large amounts of large woody debris occur throughout the creek, and the dominant streambed substrate consists of boulders, large cobble, and gravel (HDR 2016b).</td>
</tr>
<tr>
<td>EFMC (&quot;Blowout Creek&quot;)</td>
<td>Mine Site</td>
<td>Presence-CS</td>
<td>The EFMC, also known as “Blowout Creek,” is a tributary to Meadow Creek that has been severely impacted as a result of legacy mining-related activities and the failure of a dam constructed across its stream channel (Midas Gold 2016a). The dam was constructed in 1929 to supply hydroelectric power for historical milling operations. The dam failed in 1965 due to record snow melt and runoff rates, depositing large volumes of sediment into Meadow Creek, the East Fork SFSR, and the Yellow Pine pit lake (MWH 2017). This stream is considered to be the largest source of sediment to the East Fork SFSR in the analysis area. The middle reach of EFMC flows through a lateral glacial moraine that eroded during the dam failure and is still considered unstable as it continues to deposit sediments into Meadow Creek and the East Fork SFSR. Upstream of this middle reach, East Fork Meadow Creek has a low-gradient pool-riffle reach flowing through a large meadow. This reach is incised and continues to headcut in response to</td>

<tr>
<td>Garnet Creek</td>
<td>Mine Site</td>
<td>Presence-None known</td>
<td>Garnet Creek is a narrow, shallow, moderate-gradient tributary to East Fork SFSR approximately 0.3 mile downstream from the Meadow Creek confluence. The creek has been severely modified over the past 100 years to accommodate mining-related activities. It is still influenced by legacy mining infrastructure that was located across and adjacent to the stream channel, including portions of a town site; and is currently routed through several man-made ditches (Midas Gold 2016a). Garnet Creek flows through an 85-foot-long corrugated metal pipe culvert near its confluence with the East Fork SFSR that presents a partial barrier to fish (HDR 2016b).</td>
</tr>
<tr>
<td>Midnight Creek</td>
<td>Mine Site</td>
<td>Presence-None known</td>
<td>Midnight Creek is a small tributary of the East Fork SFSR. The lower portion of the creek has as a narrow channel with extremely high gradient (approximately 90 %) and dense overhanging vegetation. The high gradient presents a complete fish passage barrier to fish (HDR 2016b). Midnight Creek has been impacted by legacy mining activities, including open-pit mining, waste rock dumps, and road construction (Midas Gold 2016a).</td>
</tr>
<tr>
<td>Unnamed Tributary (&quot;Hennessy Creek&quot;)</td>
<td>Mine Site, Access Roads</td>
<td>Presence-None known</td>
<td>Hennessy Creek historically flowed into the East Fork SFSR downstream of the Yellow Pine pit lake, but it has been diverted to flow into the East Fork SFSR downstream of Sugar Creek. It is a narrow, low-flow stream that flows in a constructed ditch alongside McCall-Stibnite Road (CR 50-412), and then through a subterranean section under an adjacent waste rock dump before passing through a very high-gradient reach into the East Fork SFSR. The creek is not expected to support upstream fish passage because of an average channel gradient of 37 percent at its mouth (HDR 2016b). Hennessy Creek is densely vegetated and shallow. The lower portion of Hennessy Creek has been significantly impacted by legacy mine-related activities, including stream diversion, road construction that buried the stream channel, and mining infrastructure (Midas Gold 2016a).</td>
</tr>
</tbody>
</table>

¹ The dam failure. There are few trees, and the banks have abundant grasses. The dominant streambed material is sand and gravel (MWH 2017). The EFMC headwaters are high gradient (4 to 20%) with cascades, high-gradient riffle, and plunge-pool habitat.

Immediately downstream of the historical dam location, the creek has a slightly steeper (8 to 20%) gradient and is composed of cascade habitat. Near the confluence with Meadow Creek, the EFMC passes through a multi-thread and unconfined alluvial fan with a 4 to 8 percent gradient. Sediment from the unstable slopes immediately upstream may contribute to the formation and maintenance of this alluvial fan.

3.11.4.5 Wetlands Functions and Values

This section summarizes the wetland functional assessments that have been conducted in the analysis area (watershed condition indicators, which include stream function, are documented in Section 3.12 and in the Fish Resources and Fish Habitat Specialist Report [Forest Service 2022i]). Wetland functions are self-sustaining properties of a wetland ecosystem that exist in the absence of societal values and relate to ecological significance without regard to subjective human values. Flood attenuation and provision of off-channel fish habitat are examples of wetland functions. Wetland values are those elements of a wetland that are valued by humans, such as flood hazard reduction or recreational/hunting uses (Berglund and McEldowney 2008). Wetland functions and values were assessed to evaluate the condition of existing wetland resources so that the potential impacts of activities associated with the SGP can be understood and disclosed.

The MWAM ranks wetland functions in four categories: I through IV, with Category I having the highest functional value. Descriptions of relevant categories are as follows (Berglund and McEldowney 2008):

- **Category I** wetlands are of exceptionally high quality and generally are rare to uncommon in the state or are important from a regulatory standpoint. They can provide primary habitat for sensitive species, represent a high-quality example of a rare wetland type, provide irreplaceable ecological functions, and/or exhibit high flood attenuation capability, or are assigned high ratings for most assessed values and functions.
- **Category II** wetlands are those that provide habitat for sensitive plants or wildlife, function at very high levels for wildlife/fish habitat, are unique in a given region, or are assigned high ratings for many of the assessed functions and values but are more common than Category I wetlands.
- **Category III** wetlands are common and generally are less diverse than Category I and II wetlands. They can provide many functions and values, although they may not be assigned high ratings for as many parameters as are Category I and II wetlands.
- **Category IV** wetlands generally are small, isolated, and lack vegetative diversity. These sites provide little in the way of wildlife habitat and often are indirectly disturbed.

Per the assessments conducted by HDR and Tetra Tech, 1 of the 21 evaluated wetland AAs rated as Category IV, 17 rated as Category III, and 3 rated as Category II (Tetra Tech 2021c, Forest Service 2022h; **Figure 3.11-2**).

Depending on the specific wetland being evaluated, up to 11 functions/values can be evaluated for each assessment area (AA) using MWAM (Berglund and McEldowney 2008) including:

- **Habitat for federally listed or proposed threatened or endangered plants or animals**: Whether or not an AA is known to or suspected to function as habitat for species receiving protection under provisions of the ESA.
- **General wildlife habitat**: The general potential to provide wildlife habitat based on evidence of wildlife use and existence of generally desirable habitat features.
- **General fish habitat**: The general fish habitat quality. This function is assessed only if the AA is used by fish or if the existing situation is correctable such that the AA could be used by fish (e.g., fish use is blocked by inaccessible culvert or another barrier).
- **Flood attenuation:** The capability of wetlands in the AA to slow and disperse the potentially hazardous flow energy during high-water or flood events. This parameter only applies to AAs that occur within or contain a discernable floodplain.
- **Long- and short-term surface water storage:** The potential of the AA to capture, retain, and make available surface water originating from flooding, precipitation, upland surface (sheetflow) or subsurface (groundwater) flow.
- **Sediment/nutrient/toxicant retention and/or removal:** The ability of the AA to retain sediments and retain and remove excess nutrients and toxicants. This function is sometimes referred to as “water quality improvement.” This parameter only applies to wetlands with potential to receive sediments and excess nutrients or toxicants through influx of surface water, groundwater, or direct input.
- **Sediment/shoreline stabilization:** The ability of an AA to dissipate flow or wave energy, reducing erosion. This function is only assessed if a wetland within an AA occurs on the banks for a river, stream, or other natural or manmade channel, or occurs on the shoreline of a standing water body that is subject to wave action.
- **Production export/terrestrial and aquatic food chain support:** The potential of an AA to produce and export food and/or nutrients for both terrestrial and aquatic organisms.
- **Groundwater discharge/recharge:** The potential for groundwater discharge and recharge at the AA.
- **Uniqueness:** The general uniqueness of an AA in terms of its replacement potential and habitat diversity, relative abundance in the same major watershed basin, and degree of human disturbance.
- **Recreation/education potential:** The general potential of an AA to support recreation or education activities.

Assessed wetlands at the mine site generally exhibit moderate to high levels of disturbance from historic mining activity, erosion, and fire. They do not support known populations of ESA-listed threatened or endangered plant species (HDR 2013, 2014a, 2014b; Tetra Tech 2018); however, potential habitat and occurrences of Forest Service Sensitive and Forest Watch plant species do occur in wetlands near the SGP (Section 3.10). In addition, metal concentrations in some wetlands at the mine site exhibit the influence of the historical mining activity primarily through elevated arsenic and antimony concentrations (HDR 2017f).

Many of these wetlands were noted during surveys as having the potential to provide habitat for a variety of wildlife species managed by the Forest Service because of their sensitivity, including northern leopard frogs, fishers, boreal owls, western toads, black-backed woodpeckers, northern goshawks, and wolverines (Tetra Tech 2018). Wetlands rated as Category II generally received high scores due to the provision of habitat associated with sensitive species with potential to occur in the area (Section 3.13).

Wetlands on slopes, generally resulting from groundwater seepage, function to deliver water, sediment, and nutrients to valley bottom wetlands below. These typically exhibit less water filtration or flood storage functions because water moves through these wetlands without being detained. However, they often provide valuable habitat for terrestrial species, and they can contribute cool water to wetlands and streams in the valley bottoms.

Wetlands located along valley bottom drainages, both on and off the mine site, have the potential to provide water quality, flood storage, and fish habitat functions. These streamside wetlands filter flowing water during high flow events when water is most likely to contain fine sediments that can be harmful to fish. Given the history of mining activity and historical tailings deposits at the mine site, these water quality functions are an important aspect of stream health, both at, and downstream, of the mine site. During high flows, streamside wetlands also provide off-channel refuge for small fish that seek such areas when currents in the main channel become too strong for them.

A summary of the primary functions provided within each AA and the functional assessment scores for each AA can be found in Appendix A of the SGP Wetland and Riparian Areas Specialist Report (Forest Service 2022h).

3.12 Fish Resources and Fish Habitat

3.12.1 Introduction

This section describes the fish resources and fish habitats in the analysis area of the SGP under existing (baseline) physical, chemical, and environmental conditions. While all fish species are of management interest, four special status salmonids (i.e., fish in the family Salmonidae, which includes salmon, trout, and whitefish) are of particular resource management interest because of their status as federally listed fish or fish of management concern to the Forest Service or State of Idaho. Of the four fish species, three are federally listed as threatened species under the ESA: summer Chinook salmon, Snake River Basin steelhead, and Columbia River bull trout. Also, the Payette Forest Plan (Forest Service 2003a) has designated bull trout as a MIS. In addition, the Forest Service (Intermountain Regional Forester) has identified the westslope cutthroat trout as a Forest Service sensitive species.

3.12.2 Fisheries and Aquatic Habitat Resources Area of Analysis

The analysis area for fish and fish habitat includes the area where effects (direct/indirect) may be caused by the proposed activities (FSH 1909.15, 15.2a). The analysis area encompasses all areas in which fish resources and fish habitat may be affected directly or indirectly by the SGP, and not merely the immediate area involved. The analysis area is located in the SFSR hydrological subbasin and the North Fork Payette River hydrological subbasin (Figure 3.12-1). The analysis area for fish resources also includes all of the watercourses (i.e., streams and rivers) and waterbodies (i.e., lakes, reservoirs) in the 12-digit HUC subwatersheds that overlap the SGP area.

In the SGP analysis area the hydrologic units of relevance are, from largest to smallest:

- Salmon River “Basin” (HUC 170602) and Middle Snake-Boise “Basin” (HUC 170501);
- SFSR “Subbasin” (HUC 17060208) and North Fork Payette River “Subbasin” (HUC 17050123);
- Numerous “Watersheds” within each subbasin (i.e., Upper East Fork Salmon River Watershed (HUC 1706020804); and
- Numerous “Subwatersheds” within each watershed (i.e., Headwaters East Fork SFSR Subwatershed (HUC 170602080201). Subwatersheds are sometimes referenced as “6th field” or “HUC 12” due to the 12-digit numerical code assigned to each.
The physical footprint of the SGP where mining is proposed (i.e., the proposed “mine site” footprint) occurs within two subwatersheds: Sugar Creek and Headwaters East Fork South Fork Salmon River (Figure 3.12-2), labeled numbers 5 and 6 on Figure 3.12-1. Immediately downstream of these two subwatersheds is the adjacent No Mans Creek-East Fork South Fork Salmon River subwatershed that also is discussed in this section (HUC 170602080206), which is labeled number 4 on Figure 3.12-1. This latter subwatershed is within the analysis area, but not within the proposed mine site.

The analysis area for fish resources also includes all of the watercourses (i.e., streams and rivers) and waterbodies (i.e., lakes, reservoirs) in the 12-digit HUC subwatersheds that overlap the SGP area. Because the majority of the activities and disturbance would occur at the mine site, which is located in the SFSR subbasin, greater emphasis is placed on describing the affected environment within this subbasin. However, relevant habitat conditions in other subbasins, watersheds, and subwatersheds that may be impacted by SGP activities also are described, as appropriate.

The SGP affects watersheds within the analysis area differently depending on the activities proposed for each area. The majority of the mining activity occurs within the headwaters of the East Fork SFSR subwatershed (HUC 170602080201). In this subwatershed, surface water conditions are affected by ground disturbance, development of mine facilities, and water abstraction for mine dewatering, contact water management, and consumptive use (see Section 4.12.2.2). As a result, stream flows in the watershed would be reduced by up to 30 percent during operations. While project design features and regulatory requirements maintain water chemistry conditions, removal of riparian shading increases predicted stream temperatures by up to 6.6°C until a time that restoration efforts would effectively shade stream flows and reduce temperatures toward baseline conditions. When the tools utilized to evaluate fish habitat (e.g., intrinsic potential, occupancy, and flow productivity modeling) are applied to these to the forecasted flow and temperature conditions in the headwaters of the East Fork SFSR watershed, they indicate a change from existing conditions.

Under the SGP, there would be limited mining activity in the Sugar Creek watershed (HUC 170602080202) with most of the effects associated with diverting the West End Creek around the West End pit (see Section 4.12.2.2). West End Creek is not fish bearing and contributes relatively minor flow volumes to Sugar Creek. Predicted flow reductions in Sugar Creek attributable to the SGP would be typically less than 1 percent with a maximum monthly difference of 3 percent. Predicted stream temperature changes would be between 0.1 and 0.3°C, with maximum summer temperatures ranging from 15.5°C to 15.7°C compared to a baseline temperature condition of 15.4°C. Application of fish habitat evaluation tools to these conditions in Sugar Creek would not indicate an observable change from existing conditions. For the other watersheds in the analysis area, SGP-related effects are associated with site access and transportation which are not expected to affect streamflow and temperature conditions to the degree that fish habitat evaluation tools would indicate change from existing conditions.

Because of the minimal SGP effects anticipated to Sugar Creek, the focus of the environmental consequences analyses (Section 4.12) is on the headwaters of the East Fork SFSR.

3.12.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to Fisheries and Aquatic Resources. Additional descriptions of these regulations can be found in the SGP Fisheries and Aquatic Resources Specialist Report (Forest Service 2021).

Land and Resource Management Plan: The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired conditions for wildlife and wildlife habitat and include various objectives, guidelines, and standards for this purpose.

Portions of the BNF are administratively managed by the PNF due to location. Forest Service regulations and the Forest Plans (Forest Service 2003a, 2010a) provide guidance on resource management on NFS lands. The SGP is located in PNF Management Area 13 (Big Creek/Stibnite) and in BNF Management Areas 17 (North Fork Payette River), 19 (Warm Lake), 20 (Upper Johnson Creek), and 21 (Lower Johnson Creek), which are described in the respective Forest Plans. In addition, Appendix B of both the Payette and Boise Forest Plans provides NEPA guidance with respect to evaluating the ecological functionality of aquatic resources in the analysis area using Watershed Condition Indicators (WCI) under existing baseline conditions because they may be affected by the SGP.

U.S. Army Corps of Engineers 404 Permit: Under Section 404 of the CWA (33 United States Code [USC] 1344), a DA, USACE permit is required for the discharge of dredged and/or fill material into WOTUS. This would include discharges of dredge and/or fill material associated with activities, such as the construction of road crossings, water diversions, waste rock disposal in a stream, and other facilities associated with the SGP’s construction, operation, and closure and reclamation.

Endangered Species Act Section 7 Consultation: The ESA (16 USC 35 1531 et seq. 1988) provides for the protection and conservation of threatened and endangered species and their Critical Habitats. Section 7 of the ESA (16 USC 1531 et seq.) requires all federal agencies to consult with the USFWS and/or the NMFS or NOAA Fisheries, collectively known as “the Services”, which share regulatory authority for implementing the ESA. Federal agencies must submit a consultation package for proposed actions that may affect ESA-listed species, species proposed for listing, or designated Critical Habitat for such species. The USFWS generally manages ESA-listed terrestrial and freshwater plant and animal species, while NOAA Fisheries is responsible for marine species, including anadromous fish.

“Critical habitat” is defined by the ESA as specific areas within the geographical area occupied by listed species at the time of listing that contains the physical or biological features essential to conservation of the species and that may require special management considerations or protection (50 CFR 424). Critical habitat also may include specific areas outside the geographical area occupied by the species if the agency determines that the outside area itself is essential for conservation of the species.

The first step in the consultation process is an “informal” consultation with one or both of the Services to initially determine if the proposed action is likely to affect any listed species, species proposed for listing, or designated Critical Habitat in the analysis area. The federal agency taking the action or the “action
agency” (i.e., the Forest Service and the USACE in the case of the SGP) may prepare a BA (or designee, a non-federal representative to prepare the BA acceptable to the agency under federal regulation) to aid in determining a project’s effects on listed or proposed species or designated Critical Habitat. If the action agency determines that the action is likely to adversely affect ESA-listed or proposed species or designated Critical Habitat, then the action agency enters into “formal” consultation (or “conference” for species proposed for listing). The USFWS and/or NOAA Fisheries then prepare(s) a Biological Opinion and determines whether the action is likely to jeopardize the continued existence of the species or adversely modify designated Critical Habitat. If there is any anticipated “incidental take” (50 CFR 402.02 [defining “take”]) of a species, one or both of the Services must issue an Incidental Take Statement that includes terms and conditions and reasonable and prudent measures that must be followed to eliminate or minimize impacts to the species or its designated Critical Habitat.

**Sustainable Fisheries Act (Essential Fish Habitat):** In response to growing concern about the status of fisheries in the U.S., Congress passed the Sustainable Fisheries Act of 1996 (P.L. 104 297) to amend the Magnuson-Stevens Fishery Conservation and Management Act (P.L. 94-265), the primary law governing marine fisheries management in the federal WOTUS. NOAA Fisheries is responsible for protecting habitats important to federally managed marine species, which include anadromous Pacific salmon that occur in the SGP analysis area. Federal agencies must consult with NOAA Fisheries concerning any action that may adversely affect “Essential Fish Habitat” (EFH) pursuant to the amended Magnuson-Stevens Fishery Conservation and Management Act and its regulations (50 CFR 600). The Act defines EFH as habitats necessary to a species for spawning, breeding, feeding, or growth to maturity, which includes marine and riverine migratory corridors, spawning grounds, and rearing areas of Pacific salmon species. Given the SGP’s geographic location, Chinook salmon (Oncorhynchus tshawytscha) is the only species that has designated EFH within the SGP analysis area. As defined by the regulations, EFH includes “all streams, estuaries, marine waters, and other waterbodies occupied or historically accessible to Chinook salmon in Washington, Oregon, Idaho, and California” (50 CFR 660.412(a)). EFH is coincident with designated critical habit for Chinook salmon within the analysis area.

**Fish and Wildlife Coordination Act:** The Fish and Wildlife Coordination Act generally requires that federal agencies consult with the USFWS, the NMFS, and State wildlife agencies for activities that control or modify waters of any stream or bodies of water, in order to minimize the adverse impacts of such actions on fish and wildlife resources and habitat. This consultation is generally incorporated into the process of complying with NEPA, Section 404 of the CWA, or other federal permit, license, or review requirements. The Fish and Wildlife Coordination Act provides that wildlife conservation shall receive equal consideration and be coordinated with other features of a project.

The term “wildlife resources” is explicitly defined to include “birds, fishes, mammals, and all other classes of wild animals and types of aquatic and land vegetation upon which wildlife is dependent” (16 USC 666 (b)). Further, the Fish and Wildlife Coordination Act states that reports determining the possible damage to wildlife resources and an estimation of wildlife loss shall be made an integral part of any report prepared or submitted by the action agency with permitting authority (16 USC 662 (b), (f)).
Idaho Department of Water Resources – Stream Channel Protection Program: The Idaho Stream Channel Protection Act (Idaho Code Title 42, Chapter 38) requires that the stream channels of the state and their environments be protected against alteration for the protection of fish and wildlife habitat, aquatic life, recreation, aesthetic beauty, and water quality. The Idaho Stream Channel Protection Act applies to any type of alteration work done inside the ordinary high-water mark of a continuously flowing stream and requires a stream channel alteration permit from IDWR before commencing any work that would alter the stream channel. This means that the IDWR must approve, in advance, any work that is conducted within the beds and banks of continuously flowing streams (i.e., perennial streams). Stream channel alteration permitting requires a joint-permit application process with IDWR, the IDL, and the USACE.

Idaho Department of Fish and Game – Scientific Collection Permit and Fish Transport Permit: The IDFG requires a Scientific Collection Permit for any handling of fish that is not related to sportfishing with a state fishing license. The salvage and transport of fish by vehicle between capture and release sites for the proposed SGP is expected to require a fish transport permit.

3.12.4 Affected Environment

The following subsections describe the existing conditions of fish species, particularly Chinook salmon, steelhead, bull trout, and westslope cutthroat trout, and their habitat, as well as an overview of fish densities and watershed condition indicators (WCIs). Modeling tools are utilized to characterize fish habitat based on application of threshold criteria to available data for the site or other Idaho streams. In general, modeling tools are limited by the assumptions and data they employ and may not match field observations precisely. However, the modeling tools are utilized to form a basis for consistent comparisons between habitat criteria, existing conditions, and forecasts of future conditions.

Perpetua funded aquatic resources baseline studies from 2012 to 2020 specifically for the SGP within the mine site area and along the Burntlog Route area (AECOM 2020a). Fish data was collected through snorkel surveys, electrofishing, videography, and environmental Deoxyribonucleic Acid (eDNA) sampling (MWH 2017; Stantec 2018, 2019). Figures 3.12-3a and 3.12-3b show the location of these surveys. In 2015, fish tissue was collected to check for metal concentrations and DNA analysis.

Field investigations to characterize existing aquatic physical habitat in the mine site area and along the Burntlog Route area were performed between 2012 and 2020 (Great Ecology 2018; HDR 2016c; Rio ASE 2019a, 2020b; MWH 2017; Stantec 2018, 2019, 2020; Watershed Solutions Inc. 2021) (Figure 3.12-4). These investigations collected information on aquatic habitat parameters, such as water temperature, substrate size, substrate embeddedness, surface fines, channel geometry and physical attributes, large woody debris, and pool frequency. Stream habitat condition surveys, following the PACFISH/INFISH Biological Opinion (PIBO) protocols, collected information on bankfull width, wetted width, bank stability, sediment size, stream gradient, pool dimensions, and large woody debris.
3.12.4.1 Fish Species

The four federally listed or Forest Service sensitive fish species (i.e., special status fish species) known to be present in the analysis area are Chinook salmon, steelhead trout (*Oncorhynchus mykiss*), bull trout (*Salvelinus confluentus*), and westslope cutthroat trout (*Oncorhynchus clarkia lewisi*). Chinook salmon, steelhead, and bull trout are all federally listed as threatened under the ESA, and westslope cutthroat trout is a Forest Service sensitive species. Bull trout is also a Forest Service MIS on the PNF and the BNF and are among the most sensitive to changes in environmental variables, such as water temperature, sediment, or contaminants.

Other native fish species found within the analysis area include mottled sculpin (*Cottus bairdii*), longnose dace (*Rhinichthys cataractae*), speckled dace (*Rhinichthys osculus*), redside shiner (*Richardsonius balteatus*), mountain whitefish (*Prosopium williamsoni*), Pacific lamprey (*Entosphenus tridentatus*), and mountain sucker (*Catostomus platyrhynchus*). A list of every fish species documented in the analysis area, including non-native fish introduced to the area is provided in AECOM 2020f.

**Chinook Salmon**

Status

The Snake River spring/summer-run Chinook Salmon Evolutionary Significant Unit was listed as threatened under the ESA in 1992 (57 Federal Register 14653). Most Chinook salmon in the analysis area are considered “summer-run” fish (NMFS 2017). These fish are found throughout the analysis area, including naturally in the SFSR subbasin and the East Fork SFSR drainage upstream to the Yellow Pine pit lake within the mine site and upstream of the Yellow Pine pit when transplanted as discussed below.

A cascade with a current slope of 22 percent, caused by legacy mining activities, located upstream of Yellow Pine pit lake is a barrier to further upstream natural migration for adult Chinook salmon. Juvenile fish, however, can move downstream through the cascade because adult Chinook salmon have been reintroduced upstream of the Yellow Pine pit lake by the IDFG. Spawning-ready adult Chinook salmon are periodically translocated from the SFSR to upstream of the barrier with support from the Nez Perce Tribe.

Historically, the Snake River was considered the Columbia River Basin’s most productive drainage for salmon, supporting more than 40 percent of all Columbia River spring/summer Chinook salmon (Fulton 1968; NMFS 1995 in NMFS 2017). Currently, the stock has been severely depleted from a variety of activities, including hydropower systems, hatcheries, harvest, fish passage, and pathogens/predation/competition. Chinook salmon remain at risk of becoming endangered within 100 years (NMFS 2017).

The proposed status for the East Fork SFSR population is considered “maintained,” indicating there is a moderate (25 percent or less) risk of extinction over 100 years (NMFS 2017).

Critical Habitat and Essential Fish Habitat

Critical habitat for Chinook salmon was originally designated in 1993 (58 Federal Register 68543) and re-designated in 1999 (64 Federal Register 57399). As defined, designated Critical Habitat includes all “river reaches presently or historically accessible (except reaches above impassible natural barriers (including Napias Creek Falls [Napias Creek tributary to the Salmon River]) and Dworshak and Hells Canyon Dams)” (64 Federal Register 57403). Thus, designated Critical Habitat includes all presently and historically accessible rivers and streams within the analysis area, except for the Payette River drainage.

Given the very broad definition of Critical Habitat for Chinook salmon, a more refined description of the affected environment for the SGP was needed. Two different sets of information were used to address this need. First, data on the distribution of Chinook salmon occurrences (fish observations and spawning redd counts) were compiled for 1985 to 2011 to determine the actual locations occupied by Chinook salmon (Isaak et al. 2017). The occurrence data was coupled with National Hydrography Dataset (NHD) flowlines (Horizon Systems 2019 [NHDPlus]). The premise was that NHD flowlines with species presence demonstrated empirical evidence of Chinook salmon Critical Habitat.

Second, available GIS data was used to model what likely is Critical Habitat for Chinook salmon within the mine site area upstream from the Yellow Pine pit (Ecosystem Science, LLC [ESS] 2019e). This approach identified a 12 percent maximum gradient (percent slope) within occupied NHD lines (Isaak et al. 2017), meaning Chinook salmon can migrate upstream through stream reaches that have a less than 12 percent gradient. Within the SGP mine site, stream segments below the gradient cut-off point were modeled as Critical Habitat (i.e., areas with steeper slopes were not identified as modeled Critical Habitat) (ESS 2019e). Currently, there is an estimated 26.5 km of modeled Chinook salmon Critical Habitat upstream of the Yellow Pine pit lake barrier (Figure 3.12-5).

The EFH characteristics important for anadromous salmon for freshwater spawning and rearing include water quality, water quantity, substrate, floodplain connectivity, forage, natural cover, and reaches free of artificial obstructions for freshwater migration (NMFS 2017). EFH has been designated for Chinook salmon within all streams and other waterbodies occupied or historically accessible to Chinook salmon (67 Federal Register 2343, 2002).

Physical and Biological Features and Recovery Plan

NMFS (2017) designated the following sites and essential physical and biological features as primary constituent elements for anadromous salmon and steelhead in freshwater:

- Freshwater spawning (water quality, water quantity, and substrate);
- Freshwater rearing (water quantity and floodplain connectivity, water quality and forage, and natural cover);
- Freshwater migration (free of artificial obstruction, water quality and quantity, and natural cover).
These physical and biological features have been designated because of their potential to develop or improve and eventually provide the needed ecological functions to support species recovery (NMFS 2017). The 2017 NMFS Recovery Plan identified recovery strategies for Snake River spring/summer Chinook salmon for the Lower East Fork SFSR and Upper East Fork SFSR watersheds.

Temperature Requirements and Baseline Conditions

Chinook salmon have different temperature requirements or limitations for their various life stages. Exceeding thresholds could impact various life-stages and could cause fish to avoid areas or even mortality. The periodicity (i.e., recurring intervals) of each life stage and the accepted stream temperature threshold ranges for various temperature considerations for each species were compiled from regulatory standards and other relevant literature into ESS 2019a, a condensed version of which is presented in Table 3.12-1.

Using the QUAL2K predicted maximum MWMT values and stream segment lengths from the Stream and Pit Lake Network Temperature (SPLNT) Model Refined Modified Proposed Action (ModPRO2) report (Brown and Caldwell 2021i), the length of proposed mine site streams within these temperature thresholds was estimated (Table 3.12-1). The QUAL2K stream segments that contain the segments in which there was modeled Intrinsic Potential (IP) habitat (discussed below) were evaluated for thermally suitable habitat (based on MWMT) for all life stages except juvenile rearing. For juvenile rearing, the QUAL2K stream segments that contain segments in which there was modeled Critical Habitat. It is important to note that the IP model applied more refined spatial scale (i.e., shorter reaches) than were applied in the SPLNT model. Hence, the stream segments evaluated for temperature could have lengths that extended beyond the ends of the segments evaluated for IP. Therefore, the lengths of habitat are not identical, meaning the length of habitat meeting the temperature thresholds may be longer than the length of habitat with IP. Additionally, modeled Critical Habitat extends to a much larger area than IP because the criteria defining Critical Habitat is based on a 12 percent gradient cut-off, whereas IP criteria are based on channel conditions, gradient, and valley bottom conditions. It is assumed that juvenile Chinook salmon are able to access a larger range of habitat conditions than the other life stages, and therefore, less restrictive habitat conditions were applied in the analysis.

The East Fork SFSR from 0.89 km downstream from the confluence with Sugar Creek to around 3.4 km upstream from the confluence with Meadow Creek (total of 8.59 km), and around 4.35 km of Meadow Creek were evaluated for the temperature thresholds. The entire 12.93 km of potential habitat is within the temperature thresholds for adult spawning and juvenile rearing; however, only 9.49 km (73.4 percent) and 3.44 km (26.6 percent) is within the water temperature threshold for adult migration and incubation and emergence. Of these total lengths, 10.92 km of suitable conditions for spawning and rearing, and all of the suitable conditions for migration and incubation and emergence are upstream from the Yellow Pine pit lake cascade barrier.

It is important to note that the creeks do experience significant diurnal variations, and that for mobile life stages (i.e., adults and juveniles), if MWMTs are above the thresholds, fish present may avoid areas within streams if they are able, such as finding thermal refuges.

**Distribution**

Chinook salmon are distributed throughout the analysis area (Figure 3.12-5); however, this section focuses on the mine site area and the travel corridor on Johnson Creek Road and the Burntlog Route. The East Fork SFSR population was historically a large population, with spawning areas throughout the East Fork SFSR mainstem and Johnson Creek (NMFS 2017). Anadromous fish passage in the East Fork SFSR upstream from the Yellow Pine pit lake was blocked in 1938 when activities for mining diverted the East Fork SFSR in surface ditches and later into a bypass tunnel (constructed in 1943). The East Fork SFSR was routed back through the Yellow Pine pit after mining ceased, but the remaining 22 percent gradient cascade, just upstream of the Yellow Pine pit lake, prevents Chinook from traveling upstream. There is a supplementation program to spawning habitat in Meadow Creek above the Yellow Pine pit, discussed below.

Chinook salmon occurrence in the analysis area varies by life stage. Adult migration occurs between May and mid-September, with most reaching the upper East Fork SFSR watershed by late July and August.
Spawning occurs from mid-July to September, with peak spawning in August, particularly in the mine site, where spawning is not typically observed before mid-August. Egg incubation begins after spawning, and emergence of larval fish occurs between January and April. Juvenile rearing occurs year-round and juvenile outmigration to the ocean occurs between mid-March to November (ESS 2019a).

Habitat for Chinook salmon is measured using two different tools – Flow productivity to determine the effect of stream flow changes on Chinook salmon productivity and intrinsic potential (IP) modeling to determine the potential for streams to support spawning and early-rearing habitat.

**Surplus Supplementation**

The Nez Perce Tribe began the Johnson Creek Artificial Propagation Enhancement Project in 1998 in response to critically low numbers of returning adult Chinook salmon to Johnson Creek (Columbia River Inter-Tribal Fish Commission 2018). The program uses only natural-origin returns for broodstock, and currently has an annual target release level of 100,000 yearling smolts into Johnson Creek (NMFS 2016).

The Nez Perce Tribe and IDFG translocated adult Chinook salmon from the SFSR to Meadow Creek (upstream from the Yellow Pine pit), but not as part of the Johnson Creek Artificial Propagation Enhancement Project. This out-planting program has been highlighted in the IDFG Fisheries Management Plan (IDFG 2019a). Between 2008 and 2017 (excluding 2014), Chinook salmon spawners were released into Meadow Creek when there are surplus adults from the McCall Fish Hatchery South Fork Salmon River Chinook Salmon Mitigation Program. It should be noted that any juvenile Chinook salmon upstream of the Yellow Pine pit lake cascade barrier were entirely human assisted; without fish translocation there are no naturally occurring Chinook salmon upstream of the Yellow Pine pit lake barrier.

**Redd Surveys**

A redd is a depression or hollow that a salmon creates in the stream substrate (i.e., bed) to deposit eggs. The Nez Perce Tribe has conducted redd surveys for Chinook salmon upstream of the Yellow Pine pit lake in the East Fork SFSR, Meadow Creek, and in other SFSR subbasin streams (e.g., Lower East Fork SFSR, Burntlog Creek, Johnson Creek, Sugar Creek, and Tamarack Creek) since 2008 (Nez Perce Tribe unpublished data 2018a; Rabe et al. 2018). Table 3.12-2 shows the number of redd counts between 2008 and 2018 in the East Fork SFSR and tributaries within or near the mine site and those that might be affected by the travel corridor on Johnson Creek Road and the Burntlog Route.

Source: Nez Perce Tribe unpublished data; Rabe et al 2018
East Fork SFSR = East Fork South Fork Salmon River; NA = Not Available; YPP = Yellow Pine pit
Redds observed upstream from the Yellow Pine pit cascade barrier are all from translocated Chinook salmon. During years when adults were translocated into Meadow Creek, redd counts varied from 24 (2017) to 128 (2016). In general, lower numbers of Chinook salmon redds were found in the East Fork SFSR, likely because Chinook salmon are translocated to Meadow Creek and tend to spawn in close proximity to their introduction sites and the fact that the fish are ready to spawn at the time of release. Chinook salmon redds documented in the East Fork SFSR (between the Yellow Pine pit lake and Meadow Creek) have ranged from 1 (2013) to 13 (2011), with an average of 5 redds per year over 11 years. The number of Chinook salmon translocated and the number of redds observed demonstrate a clear, positive relationship. As the number of adults translocated increased so did the number of redds.

Johnson Creek, a tributary of the East Fork SFSR downstream of the mine site, had the highest numbers of Chinook salmon redd counts in the Upper East Fork SFSR watershed, ranging from 193 (2008, 2011) to 376 (2014), with an average count of 207 redds per year.

Flow Productivity

The effects of flow changes on Chinook salmon productivity within the mine site area were analyzed using a flow-productivity model that was developed using the flow-productivity modeling approach for the Big Creek Water Diversion Project (NMFS 2013). Productivity (also referred to as adult or whole life cycle productivity) is estimated as the ratio of the number of returning adults to the total number of fish allowed to spawn naturally during the brood year (Morrow 2018). Therefore, productivity is a unitless measure or quantity of the number of returning adults. The SGP flow-productivity model regresses productivity against flow metrics using simple linear regression to output flow-productivity (ESS 2021).

The SGP flow-productivity model uses proxy data from nearby Johnson Creek and assumes that the physical and biological conditions in Johnson Creek are relatable to the mine site streams. However, there are many physical differences between upper East Fork SFSR and Johnson Creek, including drainage size, flow regime, and Chinook populations. Also, the SGP flow-productivity model assumes a fixed number of Chinook salmon spawners each year that occurred in Johnson Creek to occur across all of the mine sites (ESS 2021). Therefore, these flow-productivity estimates provide a rough approximation of changes in productivity due to flow within the mine site.

The flow productivity analysis predicts changes in productivity based solely on streamflow changes and it does not factor in additional habitat changes that would also occur in the analysis area (e.g., direct loss of habitat, water temperature changes, etc.). The model outputs help to show the relative effects of flow modifications on Chinook salmon productivity at the reach level. Chinook salmon productivity was assessed in four stream reaches (East Fork SFSR above Meadow Creek, East Fork SFSR at Stibnite, East Fork SFSR above Sugar Creek, and lower Meadow Creek). The lower Meadow Creek site (MC-6) was set up to supplement the system of USGS gages. MC-6 specifically examines conditions in the portion of Meadow Creek that is routed through a constructed channel to divert the stream away from historical mine waste.

The flow-productivity model outputs productivity values that are compared to baseline productivity values to calculate the predicted annual percent change in Chinook salmon productivity from baseline productivity. The baseline Chinook salmon productivity value of 1.06 was derived from productivity data.
collected on Johnson Creek (Morrow 2018). The interpretation of the predicted annual percent change in flow-productivity is based upon the baseline flow-productivity calculated with Johnson Creek data because data is not available within the mine site. Because the productivity value is greater than 1.0, if Johnson Creek were an unimpaired system, there would be slightly more returning adults than the spawning brood year.

**Intrinsic Potential**

To assist with describing the existing conditions and predicted potential changes in Chinook salmon habitat at the mine site, a site-specific IP model was developed to derive a predictive metric for streams in the mine site that could potentially support spawning and early-rearing habitat for the Chinook salmon. This model included geomorphic and hydrologic attributes, including mean annual discharge, channel gradient, and channel constraint, to estimate the latent potential of stream reaches to provide favorable habitat characteristics for spawning and early life stages. Additional details on the IP modeling effort can be found in the SGP Fish and Fish Habitat Specialist Report (Forest Service 2022i). In general, the IP is the underlying capacity (i.e., potential) of a stream to provide habitat. The IP model was used to estimate the potential for spawning and rearing habitat in the headwaters of the East Fork SFSR subwatershed *(Figure 3.12-6)*. This subwatershed encompasses the mine site where mining-related activities are proposed; which includes the East Fork SFSR and tributaries upstream from Yellow Pine pit, Meadow Creek and EFMC, East Fork SFSR and tributaries between Yellow Pine pit and Sugar Creek, and East Fork SFSR downstream from Sugar Creek. Flow reductions attributable to the project in Sugar Creek would typically be less than 1 percent with a maximum monthly difference of 3 percent. Flow differences of this magnitude would have little influence on the wetted width, bankfull width, gradient, valley bottom width, and valley width ratio parameters used to assess IP. However, Chinook salmon are known to occupy Sugar Creek under its existing IP condition which would not be measurably modified by the project.

The output from the IP model provides a classification that varies from “negligible” (minimal IP to support habitat) to “high” (likely to provide habitat) with low and medium classifications in between. See Intrinsic Potential Model Chinook Salmon and Steelhead Technical Memorandum (ESS 2019c) for a detailed description and discussion of the model and results. The IP model was used to evaluate over 51 km of stream habitat. Under baseline conditions, modeled IP stream length shows only 11.1 km of the 51 km have potential spawning and early-rearing habitat for Chinook salmon *(Table 3.12-3 and Figure 3.12-6)*. The majority of the IP habitat is rated as low potential, followed by medium and negligible, with high potential having the least amount available *(Table 3.12-3)*.

**Steelhead**

**Status**

The Snake River Basin Steelhead Distinct Population Segment (DPS) is found in the East Fork SFSR drainage and its tributaries downstream of the Yellow Pine pit lake. Steelhead were initially listed as federally threatened under the ESA in August 1997 (62 Federal Register 43937) with the geographic listing area including all natural-origin populations of steelhead in the Snake River Basin. In 2006, Snake River steelhead were subsequently reclassified as a threatened DPS (71 Federal Register 834).

The Interior Columbia Technical Recovery Team (ICTRT) identified five extant major population groups (MPGs) in the Snake River Basin steelhead DPS, which includes the Salmon River Steelhead MPG (ICTRT 2008 as cited in NMFS 2017). The Salmon River Steelhead MPG consists of 12 demographically different steelhead populations all of which are presently considered non-viable (NMFS 2017). The Salmon River Steelhead MPG includes the SFSR population (NMFS 2017), which is within the analysis area. This population is found within three major tributaries in the analysis area: the East Fork SFSR, Johnson Creek, and the Upper SFSR. The SFSR steelhead population is considered “maintained,” with a tentative moderate abundance/productivity risk and low distribution and diversity risk (ICTRT 2008). This population is targeted to achieve a proposed status of “viable,” which requires a minimum of low abundance/productivity risk.

**Critical Habitat**

The final rule designating Critical Habitat was implemented in January 2006 (70 Federal Register 52630). Critical Habitat for Snake River Basin steelhead is designated throughout much of the analysis area (Figure 3.12-7). Within the areas directly affected by construction and operations, Critical Habitat is designated in the East Fork SFSR drainage to approximately 0.4 km upstream of the confluence with Sugar Creek, including Sugar Creek, and two creeks in the Johnson Creek watershed, Burntlog Creek, and Riordan Creek. Critical habitat for steelhead is not designated upstream of the Yellow Pine pit lake; however, it is assumed that steelhead were found in the headwaters of the East Fork SFSR prior to 1938. The Yellow Pine pit lake cascade barrier precludes steelhead from migrating upstream of the Yellow Pine pit lake, however, NMFS does not consider habitat upstream from the Yellow Pine pit lake to be designated Critical Habitat for steelhead (70 Federal Register 52630).

**Physical and Biological Features and Recovery Plan**

Physical and biological features are the same as previously described under Chinook Salmon above. The 2017 NMFS Recovery Plan included recovery strategies for Salmon River steelhead.

**Temperature Requirements and Baseline**

Steelhead have different thermal requirements or limitations for their various life stages. Exceeding thresholds could impact various life-stages and could cause fish to avoid areas or even mortality. The periodicity of each life stage and the accepted stream temperature threshold ranges for various temperature considerations for each species were compiled from regulatory standards and other relevant literature (ESS 2019a), a condensed version of which is provided in Table 3.12-4.
Using the QUAL2K predicted MWMT values and stream segment lengths from the SPLNT Model Refined Modified Proposed Action (ModPRO2) report (Brown and Caldwell 2021i), the length of proposed mine site streams within these temperature thresholds was estimated. Similar to Chinook salmon, the QUAL2K stream segments that contain the segments in which there was modeled IP habitat (see Intrinsic Potential under Distribution section below) were evaluated for thermally suitable habitat for all life stages. Therefore, the lengths of habitat are not identical, meaning the length of habitat meeting the temperature thresholds may be longer than the length of habitat with IP.

Table 3.12-4 shows that of the entire 2.01 km of potential habitat is within the temperature thresholds for juvenile rearing, 0.89 of which is upstream from the Yellow Pine pit lake cascade barrier. It is important to note that the length of potential habitat for steelhead incubation is based on July MWMTs, however, there are diurnal variations and hyporheic conditions that protect the eggs and alevins reducing mortality rates. Therefore, while summer temperature thresholds may show zero miles of suitable habitat, this may not be a true representation of the conditions in the river.

It is important to note that the creeks do experience significant diurnal variations, and that for mobile life stages (i.e., adults and juveniles), if temperatures are above the thresholds, fish present may avoid areas within streams if they are able, such as finding thermal refuges.

### Distribution

Steelhead occur throughout much of the analysis area (Figure 3.12-7), but within the areas affected by construction and operation, their distribution in the East Fork SFSR, up to Yellow Pine pit where a steep high gradient riffle/cascade caused by past mining activities is thought to preclude upstream migration. Steelhead can maneuver through higher gradients than Chinook salmon; however, genetic sampling suggest such migration does not occur above the Yellow Pine pit lake.

Note: The two "Present" observations in Meadow Creek and East Fork Meadow Creek may be golden trout released in the upper watershed.
Little is known about steelhead use of the Yellow Pine pit lake, but it is likely the distribution is limited. In 2018 and 2019, only 5 and 9 *O. mykiss* were identified in Yellow Pine pit lake, respectively, and were noted as rainbow trout due to the size and time of year of capture (Brown and Caldwell 2019b, 2020b). Unlike Chinook salmon (via trap and haul) and bull trout, steelhead have not been found upstream of the Yellow Pine pit lake since the initiation of mining (given no documentation prior to mining, it is unknown if they occurred prior to mining activities). However, it is possible some migrating steelhead adults may use Yellow Pine pit lake as a holding area before migrating downstream to more suitable spawning grounds. Similarly, the lake may be used for rearing by some juvenile steelhead that have dispersed upstream from downstream spawning areas (Brown and Caldwell 2019b).

Steelhead occurrence in the analysis area varies by life stage and season. Adult migration occurs between mid-March through May. Spawning occurs from April to mid-June. Incubation/emergence occurs between April and mid-August. Juvenile rearing occurs year-round, with out-migration occurring primarily in June through and September. Life stage periodicity tables are presented in ESS 2019b.

Habitat for steelhead is measured using two different tools – Flow productivity to determine the effect of stream flow changes on Steelhead productivity and intrinsic potential modeling to determine the potential for streams to support spawning and early-rearing habitat.

*Flow Productivity*

Similar to Chinook salmon, the effects of streamflow changes on steelhead productivity within the mine site area are based upon a SGP flow-productivity model that was developed using the flow-productivity modeling approach for the Big Creek Water Diversion Project (NMFS 2013). The SGP flow-productivity model uses proxy data from the Lemhi River and assumes that the physical and biological conditions in the Lemhi River are relatable to the mine site streams. However, there are many physical differences between the upper East Fork SFSR and the Lemhi River, including drainage size, flow regime and steelhead populations. Also, the SGP flow-productivity model assumes a fixed number of steelhead spawners each year that occurred in the Lemhi River to occur across all of the mine sites (ESS 2021). Therefore, these flow-productivity estimates provide a rough approximation of changes in productivity due to flow within the mine site. Additionally, the differences in streamflow regimes, physical habitat characteristics, population sizes, and other differences between Johnson Creek and the mine site streams creates uncertainty that cannot be addressed with the available data.

The flow-productivity analysis predicts changes in productivity based solely on streamflow changes and it does not factor in additional habitat changes that would also occur in the analysis area (e.g., direct loss of habitat, water temperature changes, etc.). The model outputs help to show the relative effects of flow modifications on steelhead productivity at the reach level. Steelhead productivity was assessed in four stream reaches (East Fork SFSR above Meadow Creek, East Fork SFSR at Stibnite, East Fork SFSR above Sugar Creek, and lower Meadow Creek). The lower Meadow Creek site (MC-6) was set up to supplement the system of USGS gages. MC-6 specifically examines conditions in the portion of Meadow Creek that is routed through a constructed channel to divert the stream away from historical mine waste.
The flow-productivity model outputs productivity values that are compared to baseline productivity values to calculate the predicted annual percent change in steelhead productivity from baseline productivity. The baseline steelhead productivity value of 1.24 was derived from productivity data collected on the Lemhi River (NMFS 2013). Again, the interpretation of the predicted annual percent change in productivity is based upon the baseline productivity calculated with the Lemhi River data because data is not available within the mine site. Because the productivity value is greater than 1.0, if Lemhi River were an unimpaired system, there would be slightly more returning adults than the spawning brood year.

**Intrinsic Potential**

The IP model was applied to classify the potential for spawning and rearing habitat for steelhead in headwaters of the East Fork SFGR subwatershed (Figure 3.12-6). This area encompasses the mine site area, which includes the East Fork SFGR and tributaries upstream from Yellow Pine pit, Meadow Creek and EFMC, East Fork SFGR and tributaries between Yellow Pine pit and Sugar Creek, and East Fork SFGR downstream from Sugar Creek. Over 51 km were evaluated for IP for steelhead, and under baseline conditions, modeled IP stream length show approximately 10.7 km of potential spawning and early-rearing habitat for steelhead in the mine site area (Table 3.12-5). As shown in Figure 3.12-8, high-rated and low-rated steelhead spawning and early-rearing habitat potentially occurs throughout the East Fork SFGR and Meadow Creek and the additional section of the East Fork SFGR below the confluence with Sugar Creek.

**Bull Trout**

**Status**

The USFWS listed the Columbia River DPS of bull trout as threatened in June 1998 (63 Federal Register 31647). Bull trout are currently known to use spawning and rearing habitat in at least 28 streams within the SFSR subbasin, including Burntlog Creek, Trapper Creek, Riordan Lake, East Fork SFSR, Sugar Creek, Tamarack Creek, and Profile Creek. IDFG trend data indicates that the geographic extent of bull trout is increasing (IDFG 2005b). Potential threats to the population within the SFSR subbasin include connectivity impairment, habitat degradation, and competition from invasive brook trout (USFWS 2015a); however, fish sampling has not documented brook trout in any of the mine site streams, but this species may occur in several streams in the vicinity of the Burntlog Route (Adams et al. 2002).

**Critical Habitat**

Within the analysis area, the USFWS has designated Critical Habitat for bull trout throughout the South Fork Salmon watershed, including but not limited to in the East Fork SFSR, and in Burntlog, Cane, Cinnabar, Meadow, Tamarack, Trapper, Riordan, and Sugar creeks (75 Federal Register 63898). Figure 3.12-9 shows the occurrence locations of bull trout and designated Critical Habitat in the analysis area.

**Physical and Biological Features and Recovery Plan**

Primary constituent elements are physical and biological features that are essential to the conservation of the species. For bull trout these include but are not limited to space for individual and population growth and for normal behavior; food, water, or other nutritional or physiological requirements; cover or shelter; sites for breeding, reproduction, or rearing of offspring; and habitats that are protected from disturbance or are representative of the historic geographical and ecological distributions of a species (USFWS 2010).

The most recent 5-year status review for bull trout was published in April 2008 (USFWS 2008); however, a new 5-year review is currently in progress (85 Federal Register 14240; March 11, 2020). The 2008 review concluded that listing the species as “threatened” remained warranted range-wide in the coterminous U.S. Based on this status review, the 2010 recovery report to Congress stated that bull trout were generally “stable” range wide. Since the listing of bull trout, there has been very little change in the general distribution in the coterminous U.S.

The 2015 Recovery Plan for the Coterminous United States Population of Bull Trout (USFWS 2015a) provided recovery unit implementation plans for specific recovery units, including the Upper Snake Recovery Unit, which includes bull trout in the analysis area.

Large areas of intact habitat exist primarily in the Salmon River drainage, which is the only drainage in the Upper Snake Recovery Unit that still flows directly into the Snake River (USFWS 2015a).
Bull trout exhibit three life-history strategies in the analysis area: fluvial (stream and river dwelling, spawning in small tributaries); adfluvial (lake dwelling and river spawning); and non-migratory or resident (found in small streams and headwater tributaries). Historically, the Upper Snake Recovery Unit is believed to have largely supported the fluvial life history form; however, many core areas are now isolated or have become fragmented watersheds, resulting in replacement of the fluvial life history with resident or adfluvial forms. The USFWS identified threats to bull trout persistence as “the combined effects of habitat degradation, fragmentation and alterations associated with dewatering, road construction and maintenance, mining, grazing; the blockage of migratory corridors by dams or other diversion structures; poor water quality; incidental angler harvest; entrainment into diversion channels; and introduced non-native species” (64 Federal Register 58910).

Temperature Requirements and Baseline

Bull trout have different thermal requirements or limitations for their various life stages. Exceeding thresholds could impact various life-stages and could cause fish to avoid areas or even mortality. The periodicity of each life stage and the accepted stream temperature threshold ranges for various temperature considerations for each species were compiled from regulatory standards and other relevant literature (ESS 2019a), a condensed version of which is presented in Table 3.12-6.

Using the QUAL2K predicted MWMT values and stream segment lengths from the SPLNT Existing Conditions report (Brown and Caldwell 2018a), the length of proposed mine site streams within these temperature thresholds was estimated (Table 3.12-6). The QUAL2K stream segments that contain the segments in which there was modeled habitat with occupancy probability were evaluated for thermally suitable habitat for all life stages. However, it is important to note, an Occupancy Model (OM) developed for bull trout (see below) applied more refined spatial scale (i.e., shorter reaches) than were applied in the SPLNT model. Hence, the stream segments evaluated for temperature could have lengths that extended beyond the ends of the segments evaluated for OM. Therefore, the lengths of habitat are not identical, meaning the length of habitat meeting the temperature thresholds may be longer than the length of habitat per the OM.

The East Fork SFSR from 0.89 km downstream from the confluence with Sugar Creek to around 5 km upstream from the confluence with Meadow Creek, including Fiddle Creek (total of 12.94 km), and around 13.27 km of Meadow Creek and East Fork Meadow Creek were evaluated for the temperature thresholds.

Overall, there are 26.21 km of available habitat, none of it is within optimal thresholds for incubation/emergence, almost half of it is optimal for juvenile rearing, approximately 6 percent is within the thresholds for adult spawning.

¹ Analysis based on Fall Maximum 7 Day Average of the Daily Maximum
² Percent of stream length is based on the modeled potential habitat
³ Analysis based Summer Maximum 7 Day Average of the Daily Maximum

°C = degrees Celsius; > = greater than; % = Percent; km = kilometer; FA = Functioning Appropriately; FR = Functioning at Risk; FUR = Functioning at Unacceptable Risk; km = kilometer; YPP = Yellow Pine pit

It is important to note that the length of potential habitat for bull trout incubation is based on September MWMTs; however, there are diurnal variations and hyporheic conditions that protect the eggs and alevins reducing mortality rates. Additionally, while the length of stream above and below the Yellow Pine pit are not FA and often even FR, there are all life stages of bull trout present, which means successful reproduction is occurring. Therefore, while fall MWMTs may show zero miles of suitable spawning and incubation habitat, this may not be a true representation of the conditions in the river. Additionally, if MWMTs for mobile life stages (i.e., adults and juveniles) are above the thresholds, fish present may avoid areas within streams if they are able, such as finding thermal refuges.

Distribution

Figure 3.12-9 displays the distribution of bull trout in the analysis area. Bull trout are not found outside of the SFSR subbasin within the analysis area (Burns et al. 2005). Bull trout occupy most streams affected by both construction and operations of the SGP (MWH 2017).

A subpopulation of bull trout using an adfluvial life history strategy uses the Yellow Pine pit lake for overwintering, with downstream migration to tributaries for spawning (Hogen and Scarnecchia 2006). Hogen and Scarnecchia (2006) found bull trout overwintered in the large rivers downstream of the East Fork SFSR (SFSR and the Salmon River further downstream), and then migrated upstream to the East Fork SFSR in June and July, and further into small tributaries to spawn in August and September.
Migrants stage at the mouths of presumptive spawning tributaries from mid-July to mid-August, then migrate into tributaries to spawn from mid-August to mid-September. ESS 2019h provides more detail regarding bull trout use of the Yellow Pine pit lake.

Fluvial populations downstream from the Yellow Pine pit lake quickly out-migrate as far as the mainstem Salmon River (Hogen and Scarnecchia 2006) or move up to the Yellow Pine pit lake for overwintering. The Yellow Pine pit cascade barrier blocks upstream passage of fluvial populations. Upstream from the Yellow Pine pit cascade barrier, bull trout use either the fluvial or the resident life-history strategy. The extent of available habitat upstream of the Yellow Pine pit lake is limited by gradient barriers, as well, the access to upstream habitat by fluvial populations downstream from the Yellow Pine pit barrier is blocked.

Habitat for bull trout is measured using two different tools – Occupancy modeling to determine occupancy probability and looking at how changes in stream flow affects the amount of available habitat through the use of PHABSIM modeling.

**Occupancy Probability**

The OM is a tool used to determine the probability of a fish species occupying a particular stream reach (occupancy probability) and to predict changes in the probability given changes to site physical characteristics (Isaak et al. 2015, 2017). The OM was adapted to the scale of the mine site study area and uses data collected at the mine site. The mine site OM quantifies potential habitat for each stream reach by assigning probabilities (expressed as a percent from 0 to 100) that each of the species would occur in a given stream reach. The length of a stream reach has either a low, medium-low, medium-high, or high occupancy probability (referred to as “available habitat”), which are based on the quartile in which the occupancy probability falls within the range of results for the model year. That is, the first quartile, or the lowest 25 percent, represents a low occupancy probability, and the fourth quartile, or the highest 25 percent, represents a high occupancy probability. Greater detail regarding occupancy modeling is presented in ESS 2019f.

A distance-weighted average was used to represent the average occupancy probability of each stream segment, in other words, the usability of habitat for bull trout. This was calculated by multiplying the proportion of the OM stream reach length within the stream segment (e.g., East Fork SFSR upstream of Meadow Creek) with the occupancy probability of each OM stream reach within the stream segment.

Occupancy modeling methods originate from studies completed by the Rocky Mountain Research Station, a group of scientists funded by the USDA (Isaak et al. 2015, 2017). The occupancy modeling was based on three site physical characteristic variables: stream discharge (i.e., flow), summer stream temperature, and reach slope (Isaak et al. 2017). As part of the Rocky Mountain Research Station studies, data on stream reach variables for large stream networks in the Rocky Mountains (primarily in Idaho and western Montana) were fit to bull trout and westslope cutthroat trout occurrence datasets (presence/absence data) to create parameter estimates used in a logistic regression model. The resulting parameter estimates of the model can be used to estimate occupancy probabilities for specific areas within any given stream reach where stream flow, summer water temperatures and reach slope are known. For example, an occupancy probability of 10 percent implies that a species will be present in one out of every ten reaches with similar characteristics (temperature, flow and slope) across the region (Rocky
Mountains) used to fit the model. Understanding the distinction between the scale of the Isaak et al. 2017 model and the scale of the SGP OM model is important for placing the results in context.

A site-specific OM was developed to employ the logistical regression derived from the Rocky Mountain Research Station study to estimate probabilities for both bull trout and westslope (ESS 2019f): East Fork SRSR upstream from the Meadow Creek confluence; Meadow Creek including the EFMC; East Fork SFSR upstream from the Yellow Pine pit lake and the Meadow Creek confluence, and the East Fork SFSR from the Yellow Pine pit lake and the Sugar Creek confluence. The regression model utilizes parameter values for reach slope, stream discharge, and water temperature to quantify changes in occupancy probability. This model differs from other analytical approaches in this section which utilize comparisons of parameter values such as stream temperatures to threshold values. The OM model regression relates changes in occupancy probability to changes in one of the three model variables, for example, resulting in an incremental reduction in occupancy probability with an increase in stream temperature, as opposed to a complete reduction upon exceedance of a threshold value. Therefore, because the OM model applies a regression of multiple parameters to the refined stream reaches above, it may provide different results than examination of individual parameters compared to threshold values.

Lengths of habitat and distance-weighted occupancy probabilities for bull trout for each stream reach are presented in Table 3.12-7. In total, the East Fork SFSR subwatershed contains 33.9 km of habitat available for potential occupancy for bull trout, which is about 66.9 percent of the total length of stream modeled (50.6 km). Bull trout have not been observed nor their DNA detected in the upper East Fork Meadow Creek nor in Fiddle Creek (MWH 2017), so may not occur in these two systems. Passage into both the upper East Fork Meadow Creek and Fiddle Creek would not be provided as a result of the project. Therefore, while the model provides occupancy probabilities for these creeks, it does not mean that bull trout do occur, or would occur as a result of the SGP.

A distance-weighted average method was used to represent the average occupancy probability for each stream segment, shown in Table 3.12-7. To produce the distance-weighted average, the occupancy probability of each OM reach was multiplied by the proportion of the reach’s stream length to the total length of each stream segment that has some likelihood of being occupied by bull trout. Based on the model, the Headwaters East Fork SFSR subwatershed has an estimated distance-weighted average total occupancy probability for bull trout of 7.9 percent for portions of stream reaches with low to high occupancy probabilities. The relatively low occupancy probability numbers for bull trout (less than 20 percent) indicate a higher sensitivity to the model input parameters, particularly water temperature and flow.

**Stream Flow (Physical Habitat Simulation [PHABSIM])**

Physical Habitat Simulation (PHABSIM) is a modelling technique that predicts the amount of potential fish habitat in a stream or river associated with different volumes of streamflow. First developed by USFWS, the PHABSIM model is widely used as a tool to understand the relationship between streamflow and potential fish habitat. In the late 1980s and early 1990s, the Forest Service conducted a PHABSIM modeling study at several stream locations in the East Fork SFSR watershed as part of the Snake River Basin Adjudication (Maret et al. 2006). The results of this previous study are informative in understanding the potential effects of the SGP on fish habitat. PHABSIM was used for bull trout and cutthroat trout because there was not a similar productivity analysis (ESS 2019g) as was done for Chinook salmon because that is a NMFS-derived method, and therefore has only been completed for ESA species. A summary of the PHABSIM model is provided below. A detailed description of the model and results are provided in ESS 2019g.

The PHABSIM model calculates an index of the amount of microhabitat available for target organisms and life stages at different flow levels, incorporating two major analytical components: stream hydraulics and organism/life stage-specific habitat requirements. These calculations are based on three physical variables: water depth, water velocity, and substrate composition (i.e., streambed particle size). The model uses discrete values of water depth and velocity data collected at a given stream site to simulate the same variables over a broad range of stream flows of interest. Substrate does not change in the model over the range of simulated flows. For each streamflow of interest, the model converts the simulated physical variables into equivalent values of potential fish habitat. This conversion is based on a functional relationship between the three physical variables and fish habitat suitability. Separate conversions were performed in the model for different species (bull trout and cutthroat trout) and life stages of fish. Model output is expressed as Weighted Usable Area (WUA), which represents the square feet of usable habitat per 1,000 feet of stream.
To determine general and relative relationships between streamflow and habitat in the mining reaches, the PHABSIM study compared representative streams that contained similar hydrological and geographical characteristics to the stream characteristics at the proposed mine site. This comparative analysis yielded a general grouping of the PHABSIM study site and proposed mine site streams into three index categories, basically reflecting stream size and discharge: Index 1 (small streams); Index 2 (medium size streams); and Index 3 (large streams). At the proposed mine site, each stream reach (defined below) was assigned an index (Table 3.12-8). For example, Meadow Creek and the East Fork SFSR upstream from Meadow Creek are represented by Stream Index 1, both of which are similar to the Summit Creek site of the PHABSIM study.

cfs = cubic feet per second; East Fork SFSR = East Fork South Fork Salmon River; PHABSIM = Physical Habitat Simulation; YPP = Yellow Pine pit

PHABSIM model output generates a significant volume of information on the relationship between streamflow and WUA (Table 3.12-9). To simplify model output for the purposes of evaluating fish habitat effects of the SGP, two refinements were made to the model results. First, the model output used for the proposed mine site centered on the low-flow period of the year, defined as the months of August through March. Second, the WUA for different life stages of bull trout were evaluated for three key stream flows within the low-flow period: the mean discharge rate, a lower rate close to the minimum discharge rate value for the period, and a mid-point rate between the mean and minimum values (Table 3.12-9).

The quantification of potential SGP impacts on bull trout and cutthroat trout habitat, as defined by WUA, is dependent on several factors. One important factor is the predicted change in baseline flows that would occur in the various mine site stream reaches. Unique changes would occur in each reach throughout the life of the SGP. Another factor is the non-linear relationship between flow and WUA for each fish life stage. The PHABSIM model predicts separate habitat values for all species and all life stages of interest for several stream flow rates, which when viewed graphically, represent a non-linear relationship. Lastly, the PHABSIM model results are based upon WUA data collected from index streams that do not exactly represent the physical and biological conditions of the mine site stream reaches.

¹ Weighted Usable Area is defined as the sum of stream surface area within a study site, weighted by multiplying area by habitat suitability variables (most often velocity, depth, and substrate or cover), which range from 0.0 to 1.0 each, and normalized to square units (either feet or meters) per 1000 linear units.

² This value is the mean low-flow-period discharge rate.

ND: No data were available from the PHABSIM study; N/A: not applicable.
**Westslope Cutthroat Trout**

**Status**

Due to declines in distribution and abundance, westslope cutthroat trout (cutthroat trout) is designated by the Forest Service as a sensitive species. There was a petition to list westslope cutthroat trout as a threatened species under ESA (63 Federal Register 31691); however, the USFWS determined that such a listing was not warranted (65 Federal Register 20120 April 2000).

**Temperature Requirements and Baseline**

Cutthroat trout have different thermal requirements/limitations for their various life stages. The periodicity of each life stage and the accepted stream temperature thresholds/ranges for various temperature considerations for each species were compiled from regulatory standards and other relevant literature (ESS 2019a).

Overall, there is minimal habitat suitable for incubation/emergence, but a significant portion of the usable habitat is within the temperature thresholds for juvenile rearing (**Table 3.12-10**). It is important to note that the length of potential habitat for westslope cutthroat trout incubation is based on September MWMTs; however, there are diurnal variations and hyporheic conditions that protect the eggs and alevins reducing mortality rates. Additionally, while the length of stream above and below the Yellow Pine pit do not always meet the thermal requirements, there are all life stages of cutthroat trout present, which means successful reproduction is occurring. Therefore, while fall MWMTs may show less than one mile of suitable incubation habitat, this may not be a true representation of the conditions in the river. Additionally, if MWMTs for mobile life stages (i.e., adults and juveniles) are above the thresholds, fish may avoid areas within streams if they are able, such as finding thermal refuges.

Distribution

Cutthroat trout are not found outside of the SFSR subbasin within the analysis area. They are found both upstream and downstream from the Yellow Pine pit lake. The distribution of westslope cutthroat trout in the analysis area is shown in Figure 3.12-10.

Cutthroat trout spatial and temporal occurrence in the analysis area varies by life stage, (e.g., juveniles using nursery and rearing habitat or spawning adults). Adult migration occurs between mid-March and July with the peak from mid-April to mid-June. Spawning occurs from late April to July when water temperatures are near 10°C. Peak spawning is between early May and early July. Incubation/emergence occurs between mid-April and September. Juvenile rearing occurs year-round. Emigration occurs between April and December. Life stage periodicity tables are presented in ESS 2019a.

Cutthroat trout begin to mature at age three, but usually spawn first at age four or five. Cutthroat trout may be resident (non-migratory carry out all life processes in tributaries), fluvial (migratory: reside in rivers and streams and migrate to tributaries to spawn), or adfluvial (lake-dwelling and migrate to tributaries to spawn).

Recent fish sampling was performed in the Yellow Pine pit lake to provide information on relative abundance and movement of cutthroat trout (Brown and Caldwell 2019b, 2020b). A total of 32 cutthroat trout were captured over three sampling events in May, July, and September 2018, leading to only one population estimate of 50 individuals. The movement study results showed the majority of the 32 tagged cutthroat trout remained in the Yellow Pine pit lake; only four moved downstream and were not detected returning upstream. The 2019 study resulted in population estimates ranging from 33 to 101 individuals. The size structure of westslope cutthroat trout was skewed towards larger fish. Fish less than 150- to 200-millimeter fork length were not found.

Habitat for Westslope cutthroat trout is measured using two different tools – Occupancy modeling to determine occupancy probability and looking at how changes in stream flow affects the amount of available habitat through the use of PHABSIM modeling.

**Occupancy Probability**

OM was performed for westslope cutthroat trout using the same approach as bull trout. In total, the Headwaters East Fork SFSR subwatershed contains nearly 34 km of stream channel that is potential usable habitat for western cutthroat trout (Table 3.12-11), based on OM results, which is approximately 67 percent of the total length of streams in the subwatershed (50.6 km). The Headwaters East Fork SFSR subwatershed has a distance-weighted average occupancy probability of 64.3 percent for portions of stream reaches with low to high occupancy probabilities and each reach within the subwatershed are presented in Table 3.12-11. The relatively high occupancy probability numbers for cutthroat trout (mostly greater than 60 percent) indicate a higher tolerance to the model input parameters, particularly water temperature and flow.

Descriptive statistics for lengths of available habitat and occupancy probabilities by stream reach are presented in detail in ESS 2019f.

**Stream Flows (PHABSIM)**

The same PHABSIM approach previously described for bull trout was used for westslope cutthroat trout. For each of the three discharge rates and Stream Index, Table 3.12-12 provides the WUA value for four westslope cutthroat trout life stages, along with a percentage reduction in WUA relative to the mean discharge rate WUA value.

ND: No data were available from the PHABSIM study; N/A: not applicable
3.12.4.2 Fish Density

Fish density refers to the number of individuals per unit area (e.g., square meters) or volume (e.g., cubic meters). In this document, the term “linear density” is also discussed. Linear density as used here is the number of fish per linear length of stream, typically per meter. Because the wetted area of streams varies with flow, it is useful to have a metric that is non-flow dependent, (i.e., stream length).

Stream Estimates

Fish abundance data collected during snorkel surveys in the mine site area in 2015 were used in conjunction with fish mark-recapture survey data collected at the same sites at the same time to develop fish relative abundance and density estimates. The objective of comparing snorkeling abundance data to mark-recapture data was to develop a metric that could be applied to the large number of snorkeling sites evaluated from 2012 to 2015. The details of how fish densities were derived are included in AECOM 2020g.

Several approaches to estimating salmonid densities were applied to the mine site subwatersheds and these approaches are described in detail in MWH 2017 and GeoEngineers 2017. In summary, it was determined that fish densities based on the mark-recapture method represent fair to good estimates of the fish density for most stream reaches evaluated (GeoEngineers 2017). Note that this analysis determines fish densities that can be used to estimate the salmonid abundance at a specific stream reach at the time of sampling.

The results adjusting the salmonid species areal and linear densities at snorkel survey sites within and adjacent to the mine site subwatersheds from 2012 to 2015 are summarized in Table 3.12-13.

¹ Chinook salmon densities at these locations are higher than would naturally occur, as they were from translocated adults that spawned in a small, localized area.
Site IDs consisted of reaches ranging in length from 22 to 100 meters in length with most reaches set at 100 meters.
Daytime surveys only-all fish size classes combined
EFMC = East Fork Meadow Creek; East Fork SFSR = East Fork South Fork Salmon River; NP – not present.
**Yellow Pine Pit Lake Estimate**

Mark-recapture studies were undertaken at the Yellow Pine pit lake in 2018 and 2019 to evaluate movements of salmonids and to estimate population abundances (Brown and Caldwell 2019b, 2020b). Table 3.12-14 summarizes the abundance estimate results. Detailed discussions are included in Brown and Caldwell (2019b, 2020b). No estimates were made for steelhead due to the low numbers captured (i.e., five in 2018 and nine in 2019). In addition to bull trout, cutthroat trout, Chinook salmon and steelhead/rainbow trout, mountain whitefish were captured, but no abundance estimates were made.

The results indicate limited abundance of these salmonids in the Yellow Pine pit lake. Brown and Caldwell (2019b) notes that several hundred whitefish also were captured suggesting the lake can support a large number of fish given suitable habitat.

**Table 3.12-14 Salmonid Population Abundance Estimates for the Yellow Pine Pit Lake in 2018 and 2019**

Four rainbow trout were tagged but the sample size was too small for an abundance estimate.

### 3.12.4.3 Watershed Condition Indicators

This section summarizes the existing data describing the baseline aquatic habitat conditions that may be affected by the SGP within the analysis area. It includes brief descriptions of the streams that may be affected by the SGP both outside and within the mine site. The WCIs are used as a metric to compare baseline conditions to estimated changes that might be caused by projects or other events. Over the past 20 years, various fish and aquatic habitat studies have been conducted in the SFSR subbasin which have provided a better understanding of aquatic resource baseline conditions within the analysis area. Studies have been conducted by federal, state, local, and tribal agencies (e.g., PNF, BNF, IDFG, and the Nez Perce Tribe), as well as private entities (e.g., Perpetua).

**Table 3.12-15** and **Table 3.12-16** summarize the WCI data currently available along with fish species occurrence information for each watershed and subwatershed (Figure 3.12-1). Only one subwatershed (Upper Big Creek) in the Cascade Reservoir Watershed had any WCI data available for the local fish community. More WCI data are available for most of the subwatersheds in the Upper SFSR, Johnson Creek, Lower East Fork SFSR, and Upper East Fork SFSR watersheds.
The Southwest Idaho Ecogroup Matrix of Pathways and WCIs (“The Matrix”) (Forest Service 2003a, 2010a) have been applied to describe and evaluate the baseline environment for fish and aquatic resources in the analysis area. The WCI matrix was developed specifically for application in the PNF and BNF (Forest Service 2003a, 2010a) to assist in project design and analysis during NEPA assessments of proposed projects. The WCI matrix evaluates watershed ecological functions by measuring elements that reflect water quality, habitat access, channel conditions and dynamics, flow and hydrology, and other watershed conditions. Furthermore, the WCI matrix comprises a series of “pathways” by which mining, reclamation, or restoration activities can have potential effects on native and desired non-native fish species, their habitats, and associated ecological functions. This ecological functionality is broken down into three separate categories: “functioning appropriate,” “functioning at risk,” and “functioning at unacceptable risk.” Where possible, quantitative values are applied to determine the functionality. The same description of the pathways and WCIs can be found in Table B-1, Appendix B of each Forest Plan (Forest Service 2003a, 2010a).

**North Fork Payette River Subbasin Baseline**

The Cascade Reservoir Watershed is the only HUC 5th Field watershed in this subbasin (Figure 3.12-1; Table 3.12-15). Eight subwatersheds occur in this watershed that could be impacted by the SGP. Only one subwatershed, Upper Big Creek, has had a WCI analysis completed. Many of the other subwatersheds are on private land and do not have WCIs completed.

**South Fork Salmon River Subbasin Baseline**

Baseline WCI information for the SFSR subbasin for those watersheds and subwatersheds that may be directly impacted by SGP activities is summarized in Table 3.12-16.

FA = Functioning Appropriately; FR = Functioning at Risk; FUR = Functioning at Unacceptable Risk; WSC = westslope cutthroat trout
East Fork South Fork Salmon River Watershed Baseline

The East Fork SFSR watershed covers approximately 250,000 acres and enters the mainstem SFSR near the confluence of the Secesh River. Most of the watershed is administered by the Forest Service and managed by the PNF and BNF. Private land in the watershed includes small parcels of land along Johnson Creek, large legacy mines in the headwater drainages (e.g., Stibnite and Cinnabar mines), and the village of Yellow Pine. Predominant historical land uses occurring in this watershed include timber harvest and large-scale mining (Wagoner and Burns 2001 in NMFS 2016). Extensive cattle grazing also historically occurred in the Johnson Creek watershed, but federal grazing allotments have now been retired and grazing has been reduced to private lands.

Large-scale legacy mining altered stream channel conditions in the Upper East Fork SFSR watershed. The Forest Service and mine operators have since undertaken restoration work. However, habitat for migratory salmonids in the East Fork SFSR upstream of the Yellow Pine pit lake is inaccessible because legacy mining excavation of the stream channel has created a gradient barrier (Yellow Pine pit lake cascade). Although there has been a reduction in human influences since about 1950, there are still significant legacy effects that continue to impact channel conditions and fish populations. Kuzis (1997) describes the Upper East Fork SFSR watershed as follows:

“The most significant geophysical processes affecting channels in the East Fork SFSR are mass wasting and erosion. The most obvious impacts to stream channels are located at the Yellow Pine pit lake, Meadow Creek, East Fork Meadow Creek, and the Cinnabar Mine area.”

The East Fork SFSR drainage has the lowest quality habitat for sensitive and protected fish in the SFSR subbasin (Northwest Power Conservation Council 2004). Primary habitat limitations in the East Fork SFSR drainage are reduced riparian habitat and decreased streambank stability due both to road design and the extent of the existing road system; secondary limitations include reduced instream large woody debris, water quality degradation, and fish passage barriers resulting from legacy mining in the area (Northwest Power Conservation Council 2004).

All IDEQ-inventoried waterbodies at the proposed mine site (except for West End Creek) are listed under Section 303(d) of the federal CWA as “impaired” due to water quality. The causes for listing of these waters are associated with elevated concentrations of arsenic, antimony, and mercury. Each of the 303(d)-listed waterbodies has designated beneficial uses of “cold water communities,” “salmonid spawning,” and “primary contact recreation,” and all (except Sugar Creek) have designated beneficial uses of “drinking water supply.”

Wildfires have eliminated much of the tree canopy at the SGP mine site and vicinity and substantial erosion occurs (HDR 2013). In addition, the failure of a dam on the EFMC (also referred to as Blowout Creek) in 1965 resulted in extensive erosion, both upstream and downstream from the former dam and reservoir site, which in turn has led to extensive and ongoing deposition of sediment in the lower reaches of Meadow Creek and downstream in the East Fork SFSR. Currently, while concentrations of total suspended solids and turbidity are low during some months, there is seasonal variation in these concentrations associated with high flow periods when concentrations can reach moderate to high levels.
East Fork South Fork Salmon River

The East Fork SFSR is a tributary to the SFSR. The East Fork SFSR between its confluence with Sugar Creek upstream to the Yellow Pine pit lake is 1.2 km, upstream to the confluence with Meadow Creek is 6.1 km. This stream reach includes the Yellow Pine pit lake, immediately upstream of which is a long cascade (22 percent gradient) that presents a complete upstream passage barrier for all fish species including migrating Chinook salmon and steelhead. Despite the migratory barrier at the Yellow Pine pit lake, bull trout and westslope cutthroat trout are known to occur upstream of the Yellow Pine pit lake. Chinook salmon also spawn and rear in the stream reach upstream of the lake because they have been introduced there by the IDFG. Downstream of the Yellow Pine pit lake, this stream reach is accessible to all four special status salmonid species.

Between Meadow Creek and the Yellow Pine pit lake, the East Fork SFSR widens and has larger streambed material (including abundant cobble and boulders), relative to the upper East Fork SFSR. This stream reach has moderate to high stream gradients (approximately 2 to 8 percent) (HDR 2016c). Moving downstream to the confluence with Sugar Creek, the East Fork SFSR is similar in width, gradient, and substrate material as upstream, but many of the larger boulders and cobble are sharp and more angular. Based on field surveys conducted by Rio ASE (2019), there are more and deeper pools upstream of the Yellow Pine pit lake. The East Fork SFSR generally supports a healthy riparian corridor, with the exception of areas near the Yellow Pine pit lake and areas of legacy mine waste dumps along the banks upstream and downstream of the Yellow Pine pit lake.

The East Fork SFSR in this reach has been heavily impacted by legacy mining activities. In addition to the Yellow Pine pit lake, a remnant of legacy mining activities, these impacts include waste rock dumps in and adjacent to the stream channel, tailings washed down from Meadow Creek valley, roads and infrastructure within and adjacent to the East Fork SFSR channel, dam construction across the East Fork SFSR main channel, and other legacy impacts (Midas Gold 2016a).

Hennessy Creek

Hennessy Creek historically flowed into the East Fork SFSR downstream of the Yellow Pine pit lake, but it has been diverted to flow into the East Fork SFSR downstream of Sugar Creek. It is a narrow, low-flow stream that flows in a constructed ditch alongside McCall-Stibnite Road (CR 50-412), and then through a subterranean section under an adjacent waste rock dump before passing through a very high-gradient reach into the East Fork SFSR. The creek is not expected to support upstream fish passage because of an average channel gradient of 37 percent at its mouth (HDR 2016c). Hennessy Creek is densely vegetated and shallow. The lower portion of Hennessy Creek has been significantly impacted by legacy mine-related activities, including stream diversion, road construction that buried the stream channel, and mining infrastructure (Midas Gold 2016a).

Yellow Pine Pit Lake

During mining activities during the 1930s through the 1950s, the nearly 5-acre Yellow Pine pit lake was created by open pit mining while the East Fork SFSR was diverted through the Bradley Tunnel to Sugar Creek (Hogen 2002). After mining ceased in 1952, the East Fork SFSR was allowed to flow through the abandoned mine pit. The pit currently has a maximum depth of approximately 11 meters. Diverting the
East Fork SFSR back into the stream channel and pit created a long cascade with a high (22 percent) gradient that precluded fish passage upstream into the upper watershed. Therefore, all streams upstream of the Yellow Pine pit lake are inaccessible to anadromous Chinook salmon and steelhead without human intervention. The Yellow Pine pit lake is used by both fish and mammals, including Chinook salmon, bull trout, and river otters. Mountain whitefish are abundant in the lake (Brown and Caldwell 2019b and 2020b) and it supports a healthy benthic macroinvertebrate community (IDEQ 2002). Bull trout found in the Yellow Pine pit lake may be either resident (Brown and Caldwell 2020b) and/or an adfluvial life history population that use the Yellow Pine pit lake for overwintering, with downstream migration to tributaries for spawning (Hogen and Scarnecchia 2006).

The Yellow Pine pit lake is the largest feature that affects flow rates in the East Fork SFSR; however, because of its small area, it affects low flows only slightly and does not affect high flows at all (Kuzis 1997). The lake also displays thermal stratification (i.e., order), but resuspension of sediments due to turnover is not expected. The bottom velocities necessary for turnover would not be high enough for resuspension (IDEQ 2002). Fish sampling in the Yellow Pine pit lake was not included in the habitat-related aquatic baseline studies conducted by HDR (2016c) or MWH (2017).

**Midnight Creek**

Midnight Creek is a small tributary of the East Fork SFSR. The lower portion of the creek is characterized as a narrow channel with extremely high gradient (approximately 90 percent) and dense overhanging vegetation. The high gradient presents a complete fish passage barrier to fish (HDR 2016c). Midnight Creek has been impacted by legacy mining activities, including open-pit mining, waste rock dumps, and road construction (Midas Gold 2016a).

Midnight Creek was not included in the preliminary baseline study due to restricted access, but it was surveyed by Great Ecology (2018) in the supplemental assessment. There is no baseline fish use noted for Midnight Creek (MWH 2017).

**Fiddle Creek**

Fiddle Creek is a small tributary of the East Fork SFSR just upstream of Midnight Creek. Habitat conditions in the creek have been adversely impacted from legacy mine operations, road construction, and culvert installation (Midas Gold 2016a). The lower portion of Fiddle Creek also was the site of a former water storage reservoir, the construction and operation of which degraded portions of the stream.

The lower reach of Fiddle Creek has an approximate 37 percent gradient where it flows into the East Fork SFSR, creating a complete barrier to upstream fish passage (HDR 2016c). Upstream of this barrier, Fiddle Creek retains a relatively high gradient in a relatively narrow channel, with side channels (HDR 2016c). The lower portion of the creek has a thick tall-shrub overstory dominated by gray alder (Alnus incana) (HDR 2016c). The uppermost section of Fiddle Creek is natural glacial topography, flattens in gradient, and is a slower meandering stream. Large amounts of large woody debris occur throughout the creek, and the dominant streambed substrate consists of boulders, large cobble, and gravel (HDR 2016c). Westslope cutthroat trout were the only salmonids observed in Fiddle Creek or detected in eDNA surveys (MWH 2017).
**Garnet Creek**

Garnet Creek is a narrow, shallow, moderate-gradient tributary to East Fork SFSR approximately 0.5 km downstream from the Meadow Creek confluence. The creek has been severely modified over the past 100 years to accommodate mining-related activities. It is still influenced by legacy mining infrastructure that was located across and adjacent to the stream channel, including portions of a town site; and is currently routed through several man-made ditches (Midas Gold 2016a). Garnet Creek flows through a 26-m-long corrugated metal pipe culvert near its confluence with the East Fork SFSR that presents a partial barrier to fish (HDR 2016c).

Garnet Creek was surveyed by Great Ecology (2018) in a supplemental assessment. Garnet Creek cuts through a formerly burned hillside. Most of the vegetative cover along the creek is composed of grasses; however, shrubs and trees grow alongside its banks, and woody vegetation is found in the channel (MWH 2017). There is no baseline fish use noted for Garnet Creek (MWH 2017).

**Lower and Middle Meadow Creek**

Meadow Creek is a major tributary to the East Fork SFSR that flows through a flat-bottomed valley surrounded by steep mountains. Elevations range from 1.9 km above sea level in the lower reach to over 2.3 km in the headwaters. Meadow Creek has been heavily impacted by legacy mining-related activities, including deposition of tailings and spent heap leach ore, ore processing facilities, heap leach pads, and other infrastructure, stream relocation into a straightened riprap channel, and construction of an airstrip (Midas Gold 2016a). The downstream end of the valley shows remnant effects from early mining activities, along with a large outwash feature created by a dam failure in the EFMC drainage south of the site of the Meadow Creek Mine. Portions of the creek have been modified over the years to improve conditions caused by past mine operations, including the regrading and revegetation of the 2 percent gradient lower reach of the creek in 2004 and 2005.

The middle reach of Meadow Creek is an engineered channel that was constructed to bypass the SODA. The channel was lined with riprap over geotextile fabric and is confined between reinforced/engineered slopes with a gradient of less than 2 percent. This reach has a short section with a 9 percent gradient, shallow depths, and few pools, which may be a partial fish migration barrier at low flows. The channel includes low-gradient riffles, glides (section of the stream coming out of a pool) and runs. There is no side channel development or potential large woody debris recruitment.

**Upper Meadow Creek**

Upper Meadow Creek encompasses the headwaters downstream to the location of proposed TSF Buttress. Upper Meadow Creek is confined and high gradient at the most upstream extent and low gradient and unconfined immediately upstream of the SODA in lower Meadow Creek, transitioning from a gradient of 4 to 8 percent to 2 to 4 percent. Habitat is composed of riffles, step runs (sequence of runs separated by shorter riffle steps), and pools. The presence of side channels in some portions provide potential for lateral channel movement in the less confined sections. Immediately upstream of the SODA, Meadow Creek is unconfined, with a gradient less than 1 percent. The reach is composed of low-gradient riffle, step run, and pool habitat. The floodplain is active with oxbow cutoffs, side channels, and backwater features.
**East Fork Meadow Creek**

The EFMC, also known as “Blowout Creek,” is a tributary to Meadow Creek that has been severely impacted as a result of legacy mining-related activities and the failure of a dam that had been constructed across its stream channel (Midas Gold 2016a). The dam was constructed in 1929 to supply hydroelectric power for historical milling operations. The dam failed in 1965 due to record snow melt and runoff rates, depositing large volumes of sediment into Meadow Creek, the East Fork SFSR, and the Yellow Pine pit lake (URS 2000b in MWH 2017). This stream is considered to be the largest source of sediment to the East Fork SFSR in the analysis area.

The middle reach of EFMC flows through a lateral glacial moraine that eroded during the dam failure and is still considered unstable as it continues to deposit sediments into Meadow Creek and the East Fork SFSR. Upstream of this middle reach, EFMC has a low-gradient pool-riffle reach flowing through a large meadow. This reach is incised and continues to headcut in response to the dam failure. There are few trees and the banks have abundant grasses. The dominant streambed material is sand and gravel (MWH 2017). The EFMC headwaters are high gradient (4 to 20 percent) with cascades, high-gradient riffle, and plunge-pool habitat.

Immediately downstream of the historical dam location, the creek has a slightly steeper (8 to 20 percent) gradient and is composed of cascade habitat. Near the confluence with Meadow Creek, the EFMC passes through a multi-thread and unconfined alluvial fan with a 4 to 8 percent gradient. Sediment from the unstable slopes immediately upstream may contribute to the formation and maintenance of this alluvial fan.

**Headwaters East Fork SFSR**

Upstream of the Meadow Creek confluence, the East Fork SFSR is characterized by narrower channels with moderate gradient (2 to 4 percent), transitioning to higher-gradient (4 to 8 percent) step-pool habitat further upstream. Overall substrate size is generally smaller than downstream reaches, with sand, gravel, smaller cobble, and boulders. This reach of the East Fork SFSR has relatively abundant riparian vegetation and large amounts of large woody debris.

Kuzis (1997) found that the Headwaters East Fork SFSR displays evidence of a high sediment load, such as streambed aggradation (deposition of material), channel splitting, pool filling, and overbank deposits of fines. The combination of low-gradient, relatively wide valley, plentiful wood supply, and a high sediment supply have resulted in current channel conditions.

**East Fork SFSR Between Sugar Creek and Profile Creek**

The East Fork SFSR downstream from Sugar Creek is adjacent to the SGP mine site in the No Mans-East Fork SFSR subwatershed. The East Fork SFSR ranges from low-gradient habitat with pools to high gradient habitat with cascades. Substrate throughout the reach is variable, and dependent on the gradient, with the lower-gradient sections dominated by gravel and cobbles, while the higher-gradient units are dominated by large cobble and boulders. Avalanches in 2014 have resulted in high concentrations of large woody debris in the East Fork SFSR downstream from Sugar Creek (MWH 2017). In April 2019, a series of avalanches and related landslides caused extensive damage to Stibnite Road (CR 50-412), and pushed
snow, timber, and other debris into the East Fork SFSR (Midas Gold 2019a). These events were naturally occurring in burn areas and were related to rain-on-snow events.

Sugar Creek

Sugar Creek, a tributary to the East Fork SFSR, enters the river downstream of the Yellow Pine pit lake. It has a relatively low gradient. An officially closed road closely parallels Sugar Creek for nearly 3.2 km. This road may confine the movement of Sugar Creek, specifically in areas where the banks are bound with riprap rock material. Much of Sugar Creek has large aggregates of large woody debris. The dominant substrates are sand, gravel, and cobble.

This creek has widened channels, and excessive medial and lateral bar formation in response to past sediment inputs. In the 1940s, approximately 1 million cubic yards (approximately 76,455 cubic meters) of glacial overburden was removed from the East Fork SFSR channel and placed in both Sugar Creek and other parts of the East Fork SFSR (Kuzis 1997).

Sugar Creek supports spawning and rearing for all four salmonid species and represents one of the most productive fish habitats in the Upper East Fork SFSR watershed. Legacy mining-related impacts include construction of an access road adjacent to and in the stream channel, upstream sources of sediment, and mercury contamination.

Mine Site Watershed Condition Indicators

Baseline WCIs were determined for the stream reaches within the SGP mine site. Of the WCIs listed in Table 3.12-17, not all are equal in terms of evaluating the potential impacts of the SGP within the mine site. Some baseline WCIs are of historical interest, some would not be affected by the SGP, some are not well-established from a quantitative analysis perspective so they cannot be evaluated, and some WCIs are irrelevant to the SGP. For these reasons, five WCIs that have the greatest potential to accurately identify potential impacts due to the SGP were selected for detailed analysis including Water Temperature; Sediment/Turbidity; Chemical Contaminants; Physical Barriers; and Change in Peak/Base Flows. A description of each of these WCIs and their current condition is provided in Table 3.12-17.

Water Temperature

Baseline water temperatures for the SGP mine area were evaluated using a SPLNT model developed by Brown and Caldwell (2021a). This model evaluated stream water temperatures and Yellow Pine pit lake water temperatures under baseline conditions and then potential changes that may occur as a result of proposed mine operations and subsequent reclamation. See Section 4.9.2.3 for further details on the models.

Results of the SPLNT model describing existing conditions (maximum weekly summer (July) and fall (September) temperatures) are shown in Table 3.12-18.

East Fork SFSR = East Fork South Fork Salmon River; YPP = Yellow Pine pit lake barrier; EFMC = East Fork Meadow Creek

Establishing existing surface water temperature conditions at the SGP mine site was performed as part of the Surface Water Quality Baseline Study (HDR 2017f) to provide a baseline dataset for comparing future temperature changes predicted by the SPLNT model.

The SPLNT model did not account for changes to stream temperatures caused by changing climate conditions. This means the model assumed future stream temperatures would be similar to the historic water temperature data without the SGP (Brown and Caldwell 2021i). Given ongoing climate changes, modeled temperature results would likely be higher if climate change had been considered in the model. The effects of different air temperature conditions on stream temperatures were evaluated through a sensitivity analysis (Brown and Caldwell 2018a) and an uncertainty analysis (Forest Service 2022b).

The NorWeST model, produced by the Forest Service Rocky Mountain Research Station, provides a variety of scenario-based parameters that represent future stream temperatures for National Hydrography Dataset (-Plus) reaches across the western U.S. NorWeST-modeled stream temperatures are presented (Isaak et al. 2016) alongside the SPLNT stream temperatures in Table 3.12-19 and ESS 2019a to provide information regarding the possibility of changing climate conditions in the analysis area.

°C = degrees Celsius; SPLNT = Stream and Pit Lake Network Temperature
Of the NorWeST parameters, modeled stream temperatures for 1993-2011 and 2015 are the most appropriate for comparison to existing condition (baseline) SPLNT modeled stream temperatures because they most closely coincide with the data that was used to represent baseline conditions. The NorWeST data from the above timeframes most closely coincides with the baseline data, which was collected between 2012 and 2019. There are two parameters within the NorWeST dataset that predict stream temperatures based on future scenarios; they are represented by warming trajectories 2040 (2030-2059) and 2080 (2070-2099). The exact year when the SGP would be implemented is unknown; however, if construction were to begin in 2022, then Mine Year 20 would occur in 2045 (3 years construction plus 20 years of operation and closure and reclamation activities), within the NorWeSt 2040 (2030-2059) prediction timeframe. Year 112 would be outside of the predicted timeframes the NorWeSt models provide, but the predictions through 2099 are representative of the modeled long-term trend applicable to that time period. These factors were considered when interpreting modeled future temperatures, especially the further into the future the modeled water temperatures represent.

These modeling results indicate that, depending on stream reach, climate change would increase water temperatures from baseline estimates to the end of the mine operations (2030-2059) by as much as 0.1° to 2.0°C. Into the future, baseline estimates for water temperatures would increase by as much as an additional degree (2070-2099). Depending on the salmonid species, climate change may have important biological impacts that were not considered in the SPLNT modeling. The WCI criteria for water temperatures are species and life-stage-dependent (Rio ASE 2019a). The criteria also are defined as the 7-day average daily maximum water temperatures (MWMT). The WCI water temperature criteria for Chinook salmon and steelhead spawning and rearing, and bull trout spawning, incubation, and rearing, used in the WCI functional assessment are included in BioAnalysts (2019; as cited in Rio ASE 2019) and Forest Service (2003a).

**Sediment/Turbidity**

All of the stream reaches in the Headwaters East Fork SFSR subwatershed are at unacceptable risk for Chinook salmon, steelhead, and bull trout due to baseline sediment conditions (Table 3.12-17). This is due to a variety of past disturbances at the SGP mine site that are currently affecting streambank stability and erosion, and the proximity to existing roads. The matrix WCIs use surface fines as a proxy to evaluate suspended sediment, turbidity, and salmonid spawning substrate quality.

**Chemical Contaminants**

This WCI is used to evaluate chemical contamination in surface waters in the analysis area at the mine site. The description of existing conditions relies upon data collected at eight surface water chemistry monitoring locations (Figure 3.9-7) and from information provided in Section 3.9 Water Quality.

The description of chemical contaminants focuses on five constituents of concern: aluminum, copper, antimony, arsenic, and mercury. These five constituents of concern were selected because certain concentrations within the water or fish tissue can be detrimental to fish (potential effects to fish described in more detail below). Table 3.12-20 provides the baseline conditions for these constituents of concern compared to the applicable criteria. Criteria were chosen based on consultation with the USFWS and NMFS. Explanations of the analysis criteria for the five constituents are provided in Table 3.12-20 notes.
The chemical contaminants WCI, the analysis area is “functioning at risk or unacceptable risk” (Table 3.12-17) due to existing levels of legacy mining contamination. No stream on the SGP mine site is considered within acceptable risk levels for chemical contaminants. The constituents that are currently exceeding thresholds are arsenic, antimony, copper, and mercury.

Source: Midas Gold 2019c; SRK 2021b

Analysis criteria pertain to fish species. Aluminum, arsenic, and mercury criteria are based on total concentrations while copper and antimony are based on dissolved concentrations.

1. Aluminum: Lowest predicted for the SGP area based on Recommended Aquatic Life Criteria (EPA 2018g); The same water quality data as in the Biotic Ligand Model were used (Brown and Caldwell 2020c).

2. Copper criteria was derived using the Biotic Ligand Model per guidance contained in IDEQ (2017b). A conservative chronic copper standard was estimated by applying the lowest of the 10\(^{th}\) percentile chronic criteria based on regional classifications for the Salmon River Basin, Idaho Batholith, and third order streams. Per the SGP Water Quality Management Plan (Brown and Caldwell 2020a), preliminary calculations using the Biotic Ligand Model and site-specific data have produced similar values to the standard derived using these regional classifications.

3. Antimony does not have a specified NMFS or USFWS criteria and is based on EPA’s human health chronic criterion for consumption of water and organisms is 0.0056 mg/L.

4. Arsenic: NMFS (2014) directed EPA to promulgate or approve a new aquatic life criterion. In the interim, NMFS directed EPA to ensure the 0.010 mg/L human health criterion applied in all NPDES permits. USFWS (2015b) directed EPA to ensure that the 10 μg/L recreational use standard is applied in all Water Quality Based Effluent Limitations (WQBELs) and Reasonable Potential to Exceed Calculations using the human health criteria and the current methodology for developing WQBELs to protect human health.

5. Mercury: NMFS (2014) directed EPA to promulgate or approve a new criterion. In the interim, implement the fish tissue criterion that IDEQ adopted in 2005. Where fish tissue is not readily available, then NMFS specified application of a 2.0E-06 mg/L threshold (as total mercury) in the interim. USFWS (2015b) directed EPA to use the 2001 EPA/2005 Idaho human health fish tissue criterion of 0.3 mg/kg wet weight for WQBELs and reasonable potential to exceed criterion calculations using the current methodology for developing WQBELs to protect human health.

6. Of the 38 dissolved copper values reported for YP-T-1, only one value was higher than 0.00261 mg/L; therefore, it is likely that this single anomalous value was the result of a sampling, analytical, or data management error.

mg/L = milligrams per liter
**Aluminum**

Aluminum can accumulate at the surface of the gill, leading to respiratory dysfunction and disruption of salt balance, and can cause mortality (EPA 2018g). The aquatic life recommended criteria for aluminum for a site are based on site-specific conditions of pH, total hardness, and dissolved organic carbon. The EPA acute criteria for the same conditions as used in calculating the site-specific copper criteria based on the Biotic Ligand Model (Brown and Caldwell 2020b), range from 930 to 2,500 μg/L total recoverable aluminum, and the chronic criteria range from 360 to 1,700 μg/L total recoverable aluminum. The State of Idaho does not currently have a specific water quality standard for aluminum in place for the protection of aquatic life and the EPA criteria have not yet been adopted by the State of Idaho. Nevertheless, they reflect the most current knowledge of potential impacts of aluminum to aquatic life. None of the assessment nodes show an exceedance of the analysis criteria for aluminum.

**Copper**

Copper and copper compounds are acutely toxic to fish and other aquatic life at low parts per billion levels (Eisler 1991, 2000; Hamilton and Buhl 1990). Copper is essential to the growth and metabolism of fish and other aquatic life, but it can cause irreversible harm at levels slightly higher than those required for growth and reproduction (Eisler 2000). Exposure to sublethal levels of copper can have a detrimental effect on the behavior of salmonids. McIntyre et al. (2012) evaluated the effects of copper exposure on juvenile Coho salmon (*Oncorhynchus kisutch*) predator avoidance behaviors and found that the exposed juveniles were unresponsive to their chemosensory environment, unprepared to evade nearby predators, and less likely to survive an attack sequence. Salmonids are known to avoid waters with sublethal concentrations of copper, and such concentrations alter other behavior as well.

The Biotic Ligand Model-based copper criteria indicated an exceedance in Sugar Creek at YP-T-1. However, of the 38 dissolved copper values reported for YP-T-1, only one value was higher than 0.00261 mg/L; therefore, it is likely that this single anomalous value was the result of a sampling, analytical, or data management error.

**Antimony**

Known effects of antimony on aquatic organisms are more limited than for other metals and most available information pre-date the last three decades. Antimony can be toxic to aquatic life and bioaccumulate in tissues but has not consistently shown a tendency to biomagnify within aquatic food webs as other metals (Obiakor et al. 2017). Ambient water quality criteria for the protection of aquatic life have not been established for antimony. Average antimony concentrations currently exceed the analysis criteria at every assessment node except YP-T-11 in Fiddle Creek (Table 3.12-20).

**Arsenic**

Arsenic criteria are specific to the inorganic form, which is the more toxic form to aquatic life and humans. Arsenic exposure can occur through both waterborne concentrations and through dietary exposure for aquatic life and humans. In the State of Idaho, criteria exist for both the protection of human health and the protection of aquatic life. NMFS directed the human health standard be used until new aquatic life criterion can be promulgated by EPA. Arsenic can concentrate in tissues of fish, but it does not biomagnify. The effects of arsenic on fish health include enzymatic, genetic, and immune system.
failure (Kumari et al. 2017). Arsenic is a suspected carcinogen in fish and is associated with necrotic and fibrous tissues and cell damage, especially in the liver. Arsenic can result in immediate death through increased mucus production and suffocation. Other effects include anemia and gallbladder inflammation (NMFS 2014).

Arsenic concentrations currently exceed the analysis criteria at all assessment nodes except YP-T-11 in Sugar Creek (Table 3.12-20).

Mercury

Mercury in the environment originates from both natural and anthropogenic (human-caused) sources. However, regionally, the most significant source of mercury in Idaho is air deposition. Methylation is a process by which inorganic mercury is converted to the organic form (methylmercury), which can be present in the water column and is the form that bioaccumulates in tissues of living organisms. Consuming methylmercury that has accumulated in other organisms is the primary form for mercury exposure for humans. Currently, the value of 0.3 milligrams (mg) of MeHg per kilogram of fish tissue wet weight is set at a level to protect the general public from negative effects of mercury during a lifetime of exposure through the consumption of fish. It also is the human health standard of 0.3 milligram per kilogram fish tissue criterion that is protective of aquatic life (IDEQ 2005, 2018). Although the water column-based aquatic life chronic criterion for mercury in Idaho is 0.000012 mg/L (Total), the preferred value used for interpreting risks of mercury contamination to aquatic life is the fish tissue criterion of 0.3 mg/kg wet weight, the same value used for protection of human health (IDEQ 2018).

Predatory species in the food web concentrate the highest amounts of mercury in their tissues, a process called biomagnification. Salmonids in the streams and rivers of Idaho may be the dominant predator species and can concentrate mercury at levels several times that of prey species, such as algae, aquatic insects, and fish that do not feed exclusively on other fish. Generally, piscivorous fish (fish-eating) will bioaccumulate the highest concentration of mercury. Larger fish, which also tend to be older, are expected to bioaccumulate the most methylmercury.

Mercury concentrations currently exceed the 2.0E-6 mg/L analysis criteria at six of the ten nodes including in the East Fork SFSR at nodes YP-SR-10, YP-SR-8, YP-SR-6, YP-SR-4, YP-SR-2, and in West End Creek at node YP-T-6 (Table 3.12-20).

Physical Barriers

Barriers to fish passage can impact the natural movement (e.g., migration) of fish species and fish population dynamics by reducing, or completely blocking, potential habitat during certain life stages. Barriers can impact fish habitat connectivity and disrupt the natural movement of fish and block important habitat for fish during all life cycles, including spawning and rearing. Fish passage barriers were identified and described within the SGP mine site (BioAnalysts 2021). Only the East Fork SFSR downstream of the mine site and Sugar Creek are without artificial (i.e., human-made) barriers (BioAnalysts 2020). Eleven artificial barriers to fish passage and one natural barrier were identified (BioAnalysts 2020). The statuses of these barriers were identified as either complete, meaning no fish species can pass at any time of year, or partial, meaning some or all fish may pass at moderate or high flows, but not at low flows. Artificial barriers can be attributed to various actions, for example,
construction of culverts and stream alteration (BioAnalysts 2020). Of these eleven artificial barriers, six are located in non-fish bearing streams. The remaining five barriers are shown in Figure 3.12-11 and described in more detail in ESS 2019b. Table 3.12-21 presents the amount of total potential fish habitat upstream of each barrier.

BioAnalysts (2020) identified three major barriers to fish movement in the SGP mine site area: 1) the high gradient cascade in the East Fork SFSR upstream of the Yellow Pine pit lake; 2) East Fork SFSR box culvert; and 3) the high gradient cascade in Meadow Creek upstream from the confluence with the EFMC. The high gradient cascade in the East Fork SFSR upstream of the Yellow Pine pit lake is a complete barrier to natural fish passage. The other two major barriers, the East Fork SFSR box culvert and Meadow Creek barriers, are flow-dependent partial barriers that can block seasonal migration, and only hinder migration of fish that reside in or were stocked upstream of the Yellow Pine pit lake (i.e., translocated Chinook salmon).

Peak/Base Flow

USGS data were used to derive peak flow statistics for the ten major drainages in the analysis area (Figure 3.8-3). Results from the peak flow analysis were summarized in the baseline study (HydroGeo 2012b) and are presented in the Water Quantity Specialist Report (Forest Service 2022e). Peak flows were calculated for the bottom of each drainage using the USGS StreamStats program. Predicted peak flows for a 1.5-year event ranged from 1.84 cfs for West End Creek to 237 cfs for the East Fork SFSR, and for a 500-year event they ranged from 13.4 cfs to 931 cfs, respectively. Table 6-5 in the Water Quantity Specialist Report (Forest Service 2022e) provides the maximum flow predicted to occur for various return periods from a 1.5-year event up to a 500-year event.

Base stream flow data were collected in conjunction with surface water quality sampling on a monthly or quarterly basis at 32 non-USGS monitoring stations. The monitoring points were selected at upstream and downstream locations to bracket historical and potential future mining activities in the analysis area (Brown and Caldwell 2017a). Table 6-6 in the Water Quantity Specialist Report (Forest Service 2022e) provides stream flow statistics derived from baseline measurements collected between 2012 and early 2016. The mean flows calculated from this dataset for the East Fork SFSR ranged from 4.47 cfs at the farthest upstream monitoring location to 31.31 cfs at the most downstream location.

Table 3.12-22 shows average monthly stream flows during the August to March low flow period at five gaging stations and location in lower Meadow Creek in the SGP mine site streams for the years 1929 to 2017.

Climate change conditions resulting in increasing air temperatures would potentially transition snow to rain resulting in diminished snowpack and earlier season streamflow along with changes in groundwater recharge to aquifers that discharge to streams. Mean annual streamflow projections suggest a slight increase, but summer low flows are expected to decline (Halofsky et al. 2018).

### 3.13 Wildlife and Wildlife Habitat (Including Threatened, Endangered, Candidate, and Sensitive Species)

#### 3.13.1 Introduction

This section describes the existing (baseline) conditions relevant to wildlife species and supporting habitats that have the potential to be affected by the SGP.

#### 3.13.2 Wildlife and Wildlife Habitat Area of Analysis

The wildlife analysis area covers approximately 613,793 acres of land, with 253,654 acres (41 percent) on the BNF, 127,487 acres (21 percent) on the PNF, 39,988 acres (7 percent) on the Salmon-Challis National Forest (acres that would be directly impacted by the SGP are administered by the PNF), and 192,664 acres (31 percent) outside Forest Service boundaries. The analysis area is shown in Figure 3.13-1. If not discussed in this section, all other wildlife species were analyzed using the HUC 12 wildlife analysis area including Monarch butterfly.
The Canada lynx analysis area includes the seven Lynx Analysis Units (LAUs) located within the wildlife analysis area. LAUs were delineated across the PNF and BNF using fifth-level HUC boundaries, with some using sixth-level HUC boundaries, where applicable. Appendix C of the Wildlife and Wildlife Habitat Specialist Report (Forest Service 2022j) contains more information about LAUs. Figure 3.13-2 shows the Canada lynx analysis area, which includes approximately 656,493 acres as defined by the seven LAUs (i.e., Stibnite, Yellowpine, Burntlog, Landmark, Warm Lake, East Mountain, and West Mountain) and the current modeled source habitat for lynx in the Canada lynx analysis area.

NIDGS have a very limited distribution and are only known to occur in three watersheds in Idaho: Brownlee, Little Salmon, and Weiser. (Crist and Nutt 2007). Figure 3.13-3 shows the NIDGS analysis area, which is approximately 17,917 acres and consists of modeled suitable habitat within the HUC12 wildlife analysis area. NIDGS would only have the potential to occur in specific habitats of the wildlife analysis area. Appendix A of the Wildlife and Wildlife Habitat Specialist Report (Forest Service 2022j) includes more information about the habitat modeling used for NIDGS.

Habitat for the wolverine within the wolverine analysis area was modeled based on the persistent spring snow model updated for the PNF and BNF (2009-2015) for the Wolverine – Winter Recreation Research Project: Investigating the Interactions Between Wolverines and Winter Recreation study (Heinemeyer et al. 2017). In the wildlife analysis area, wolverines are most likely to use habitats with persistent spring snow cover for denning and winter range and are expected to move through areas without snow at different times of the year. Appendix A of the Wildlife and Wildlife Habitat Specialist Report (Forest Service 2022j) includes more information about the habitat modeling used for wolverine. The HUC 12 wildlife analysis area with modeled wolverine habitat is shown on Figure 3.13-4.

The analysis area for Rocky Mountain bighorn sheep (bighorn sheep) is based on the habitat model developed to quantify summer and winter habitat on the PNF. Based on known occupancy in the FCRNRW, the bighorn sheep analysis area also includes acreages in several HUC 12 watersheds on the Salmon-Challis National Forest (Figures 3.13-5 and 3.13-6).

Appendix A of the Wildlife and Wildlife Habitat Specialist Report (Forest Service 2022j) provides more information about the bighorn sheep source habitat model.

The riparian analysis area includes any water/wetland features and forested riparian areas (forest types not categorized as PVGs) within the HUC 12 wildlife analysis area. The riparian analysis area was developed to describe existing conditions and potential impacts to the Columbia spotted frog and other associated riparian species. Figure 3.13-7 shows the riparian analysis area, which is approximately 126,942 acres.

### 3.13.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to wildlife and wildlife habitat. Additional descriptions of these regulations can be found in the SGP Wildlife and Wildlife Habitat Specialist Report (Forest Service 2022j).
Land and Resource Management Plans: The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired conditions for wildlife and wildlife habitat and include various objectives, guidelines, and standards for this purpose.

The Payette and Boise Forest Plans include management direction for wildlife and wildlife habitat, including TEPC species. The Forest Plans prescribe management direction in order to achieve the desired outcomes and conditions for wildlife and wildlife habitat. Both the Payette and Boise Forest Plans have numerous goals, objectives, guidelines, and standards related to special status and general wildlife species.

Endangered Species Act: The ESA (16 USC 35 1531 et seq. 1988) provides for the protection and conservation of threatened and endangered species and their Critical Habitats. Section 7 of the ESA (16 USC 35.1531 et seq.) requires all federal agencies to consult or confer with the USFWS and/or the NMFS or NOAA Fisheries, collectively known as “the Services”, which share regulatory authority for implementing the ESA. Federal agencies must submit a Section 7 package for proposed actions that may affect ESA-listed species, species proposed for listing, or designated Critical Habitat for such species. The USFWS generally manages ESA-listed terrestrial and freshwater plant and animal species.

Migratory Bird Treaty Act (MBTA): The MBTA (16 USC 703–712) provides protection for all migratory bird species. The MBTA specifically prohibits any action to “pursue, hunt, take, capture, kill, attempt to take, capture or kill, possess, offer for sale, sell, offer to purchase, purchase, deliver for shipment, ship, cause to be shipped, deliver for transportation, transport, cause to be transported, carry, or cause to be carried by any means whatever, receive for shipment, transportation or carriage, or export, at any time, or in any manner, any migratory bird, included in the terms of this Convention . . . for the protection of migratory birds . . . or any part, nest, or egg of any such bird.” (16 USC 703). The current list of migratory bird species can be found in 50 CFR Part 10.13.

Bald and Golden Eagle Protection Act (BGEPA): The BGEPA (16 USC 668-668d) provides protection for bald and golden eagles, including prohibition of interference with normal foraging, nesting, and rearing activities. This protection is separate from any ESA designation for either species. Additionally, the USFWS has developed the National Bald Eagle Management Guidelines to advise landowners, land managers, and others who share public and private lands with bald eagles when and under what circumstances the provisions of the BGEPA may apply to their activities.

Fish and Wildlife Coordination Act: The Fish and Wildlife Coordination Act (Act of March 10, 1934) authorizes the Secretaries of Agriculture and Commerce to provide assistance to, and cooperate with, federal and state agencies to protect, rear, stock, and increase the supply of game and fur-bearing animals, as well as to study the effects of domestic sewage, trade wastes, and other polluting substances on wildlife. Amendments enacted in 1946 require consultation with the USFWS and the fish and wildlife agencies of states where the “waters of any stream or other body of water are proposed or authorized, permitted or licensed to be impounded, diverted . . . or otherwise controlled or modified” by any agency under a federal permit or license. Consultation is to be undertaken for the purpose of “preventing loss of and damage to wildlife resources.”
Habitat model inputs are within the Payette and Boise National Forests Administrative Boundaries. Input data does not exist off-Forest or on the Salmon-Challis National Forest for the models used.

Riparian Habitat Stibnite Gold Project Stibnite, ID
Migratory Birds, EO 13186 of January 10, 2001: EO 13186 Responsibilities of Federal Agencies to Protect Migratory Birds (66 Federal Register 3853; January 2001) directs federal agencies to protect migratory birds. The USDA, Forest Service, and the USFWS signed a memorandum of understanding in December 2018 that outlines a collaborative approach to promote the conservation of migratory bird populations. The memorandum of understanding between the Forest Service and USFWS was designed to complement EO 13186.

Hunting Heritage and Wildlife Conservation, EO 13443 of August 20, 2007: EO 13443 Facilitation of Hunting Heritage and Wildlife Conservation (72 Federal Register 46537, August 20, 2007) directs appropriate federal agencies to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.

State and Local Law: Idaho Code (Title 36) establishes the Idaho Fish and Wildlife Commission and the IDFG. It establishes fish and wildlife as the property of the citizens of Idaho and gives authority to IDFG to protect, preserve, perpetuate, and manage the state’s fish and wildlife resources. The Commission has approved several fish and wildlife management plans that are relevant to the SGP. These include the Idaho Mule Deer Management Plan 2008-2017, the Idaho Elk Management Plan 2014-2024, the Management Plan for the Conservation of Wolverines in Idaho 2014-2019, and the Idaho State Wildlife Action Plan.

3.13.4 Affected Environment

The following subsections describe the existing conditions of TEPC species; focal species (including Region 4 Sensitive Species and MIS); Idaho Species of Greatest Conservation Need (SGCN); big game species; and migratory birds.

3.13.4.1 General Wildlife Habitat

Existing disturbance within the analysis area includes legacy mining-related disturbance and existing roads and trails. Legacy mining-related disturbance is primarily within the SGP mine site area with an estimated 1,593 acres of existing disturbance within areas that would be encompassed by the SGP under all alternatives.

Vegetation Conditions Related to Wildlife Habitat

The Forest Service maps PVGs and existing vegetation on the PNF and BNF (Forest Service 2005a). This mapping is available only for NFS lands. Both existing vegetation and PVG mapping are useful to understand the vegetation community characteristics of a site, and as such, both datasets are referenced and used as the basis for describing existing conditions and analysis of impacts to wildlife habitat. Most focal species models applied in this analysis use a combination of PVG, canopy cover, and tree size class to define and model source habitat both within and outside historic range of variability (HRV) conditions.

Potential Vegetation Groups

PVGs are generally a description of the climax plant community (final stage in ecological succession) that could be supported by a site, as determined by abiotic conditions such as climate, soil types, hydrological conditions, and topographical aspect. PVG descriptions derived from Payette and Boise Forest Plans
(Forest Service 2003a, 2010a) are presented in the Section 3.10 and the SGP Vegetation Specialist Report (Forest Service 2022g).

**Existing Vegetation**

The Vegetation Classification Mapping and Quantitative Inventory (VCMQI) existing vegetation types (Forest Service 2016b, 2017a) can be used to describe seral-stage (intermediate ecological succession) plant community composition as it was at the time of the most recent mapping. Existing vegetation mapping typically describes the current dominant vegetative cover or species occupying a site and is frequently updated to reflect vegetation changes due to disturbance such as fire, insects, and disease.

Vegetation communities in the region are generally coniferous forests typical of high mountain regions in Idaho and the inland northwestern U.S. The most common unburned existing vegetation types in the region are lodgepole pine forests, subalpine fir forests, Douglas-fir forests, ponderosa pine forests, and Engelmann spruce forests (Forest Service 2022g). Fires routinely occur in the wildlife analysis area and surrounding forests, and as such, much of the wildlife analysis area and vicinity is mapped as burned herb lands (grasses and forbs), burned sparse vegetation, and burned forest shrublands.

Riparian habitats are present along numerous waterbodies. Existing vegetation types in the vegetation analysis area are discussed further in Section 3.10.

**Tree Canopy Cover Class**

The Forest Service tracks the canopy cover class (i.e., how dense the tree canopy is) of the various VCMQI existing vegetation types (Forest Service 2016b, 2017a), which can be further used to assess specific habitat preferences for terrestrial wildlife species. Because of past disturbance from mining activity and large wildfires, tree canopy closure is low across many portions of the wildlife analysis area.

**Tree Size Classes**

The Forest Service categorizes tree size classes (i.e., how large the trees are) of the various VCMQI existing vegetation types (Forest Service 2016b, 2017a), which can be further used to assess specific habitat preferences for terrestrial wildlife species. Tree size classes in the wildlife analysis area also have been affected by past disturbance, including fire. A small percentage of the wildlife analysis area consists of large tree size classes (greater than 20 inches dbh). Small (5 to 10 inches dbh) and medium (10 to 20 inches dbh) tree size classes are more common throughout the wildlife analysis area. Sapling (0.1 to 5 inches dbh) and non-forested tree size classes are much less prevalent.

**3.13.4.2 Threatened, Endangered, Proposed, and Candidate Species**

Four TEPC species are either known to occur, or have the potential to occur, in the wildlife analysis area, and all four have their own species-specific analysis area within the broader wildlife analysis area. These species include Canada lynx, NIDGS, wolverine, and Monarch butterfly (Table 3.13-1). An additional federal threatened species, the yellow-billed cuckoo (*Coccyzus americanus*), was considered but dismissed from this analysis. There are no documented occurrences or potentially suitable habitat for this species in the SGP area and vicinity (Strobilus Environmental 2017). Additionally, results of a query of the USFWS Information, Planning, and Conservation Online Database for the SGP area did not include this species (USFWS 2019a).

1Species Status (USFWS 2019a): T = ESA Threatened; PT = Proposed ESA Threatened; C = ESA Candidate; S = Region 4 Sensitive; MIS = PNF and BNF MIS, F = Focal Species, BG = Big Game, R4 = Region 4.
**Canada Lynx**

The Final Rule to list the Canada lynx as threatened under ESA by the USFWS was issued in March 2000 (65 Federal Register 16052). In 2000, the Canada Lynx Conservation Assessment and Strategy (LCAS) (Ruediger et al. 2000) was developed to provide a consistent and effective approach to conserve Canada lynx on federal lands. The PNF and BNF amended their existing plans in 2003 to be consistent with the LCAS.

Critical habitat for lynx was designated by the USFWS on February 25, 2009 (74 Federal Register 8616) and revised on September 12, 2014 (79 Federal Register 54781). Critical habitat for Canada lynx has been designated by the USFWS in five core units: Unit 1 in Maine, Unit 2 in Minnesota, Unit 3 in Montana and Idaho, Unit 4 in Washington, and Unit 5 in Wyoming and Montana (74 Federal Register 8616). The Idaho portion of Unit 3 is located outside the Canada lynx analysis area for the SGP in the extreme eastern border of Boundary County in the northern “panhandle” region of the state, approximately 280 miles away. No Critical Habitat has been designated on the PNF or BNF and core, secondary, and peripheral areas delineated for the Recovery Outline for the Contiguous U.S. Distinct Population Segment of Canada Lynx describe the forests as a secondary area (USFWS 2005). The LCAS updated in 2013 (Interagency Lynx Biology Team 2013) also describes the PNF and BNF as secondary areas. Secondary areas are those with historical records of lynx presence with no record of reproduction; or areas with historical records and no recent surveys to document the presence of lynx and/or reproduction. (USFWS 2005).

Canada lynx occur throughout Canada and Alaska, in the northern and central Rocky Mountains, and in the extreme northeastern and north-central U.S. Most lynx occurrences in the western U.S. are associated with mixed-conifer forest with the highest percentage (77 percent) occurring at the 4,921- to 6,562-foot elevation zone (McKelvey et al. 2000). Subalpine fir, Engelmann spruce, and lodgepole pine forest cover types in cold, moist PVGs provide the predominant habitat type for lynx (Aubry et al. 2000). Dry forest cover types, such as ponderosa pine forest, are not expected to provide lynx habitat. Typical prey species include snowshoe hares, squirrel species, grouse species, porcupines, beaver, small rodents, and even deer species opportunistically (Interagency Lynx Biology Team 2013). However, because snowshoe hare are the primary prey of lynx throughout their range, lynx distribution is closely associated with snowshoe hare distribution. Enhancing and protecting snowshoe hare habitat is a management priority in secondary areas (Interagency Lynx Biology Team 2013). Canada lynx typically use boreal forest landscapes with a mosaic of successional forest types that contain the following features (USFWS 2009):

- Presence of snowshoe hare and their preferred habitat conditions, which include dense understories of young trees, shrubs, or overhanging boughs that protrude above the snow, and mature multistoried stands with conifer boughs touching the snow surface.
- Winter snow conditions that are generally deep and fluffy for extended periods of time.
- Sites for denning that have abundant, coarse, woody debris, such as downed trees and root wads.
- Matrix habitat (e.g., hardwood forest, dry forest, non-forest, or other habitat types that do not support snowshoe hares) that occurs between patches of boreal forest in close juxtaposition (at the scale of a lynx home range) that lynx are likely to travel through while accessing patches of boreal forest in a home range.
Canada lynx habitat was mapped on the PNF and BNF and relies on specific habitat types in specific structural stages within certain PVGs, which is unlike other species models that only use PVGs with structural conditions (e.g., tree size class and canopy cover). The PNF and BNF use two classifications for lynx habitat in LAUs: “existing suitable habitat” and “source habitat capacity.” “Existing suitable habitat” meets forest criteria that is currently suitable for use by lynx and is defined by parameters such as post-burn habitat (defined to better represent horizontal cover in snowshoe hare habitat), road density, and plantation age. Habitat modeling parameters are based on previously defined relationships among vegetation, snowshoe hare, and lynx. “Source habitat capacity” has the potential to develop into suitable lynx habitat in the future. The source habitat capacity model predicts the potential for overall lynx habitat capacity, including primary (breeding) and secondary habitat. It defines acreages of vegetative communities (in selected PVGs), which include preferred habitat types such as Engelmann spruce, lodgepole pine, and mixed-conifer types with Douglas fir and subalpine fir. However, the lynx habitat models are limited by inadequate data for various habitat features (e.g., tree size class, tree canopy cover, dead and downed wood, snag density, and understory cover), and overestimate existing and source habitat capacity acreages as a result. The PNF and BNF maintain the lynx habitat classes as a spatial database for analysis using Geographic Information Systems. Table 3.13-2 summarizes the areas of existing and unsuitable lynx habitat in each LAU, and whether the LAU currently meets the Forest standard for suitable habitat.

1 Acreage based only on NFS lands. Canada lynx analysis area (656,493 acres) includes NFS and non-NFS lands.

There are approximately 102,147 acres of existing suitable habitat for Canada lynx in the PNF and BNF LAUs listed above (i.e., Canada lynx analysis area), and 220,260 acres of source habitat capacity (i.e., extent of PVGs or cover types capable of developing source habitat conditions at some point in time and within some defined area [Forest Service 2003a, 2010a]) for the PNF and BNF LAUs. Figure 3.13-2 shows existing suitable the current habitat for Canada lynx. Five of the seven LAUs are currently not meeting Forest TEPC Standard 15 (TEST15); this indicates the percentage of unsuitable habitat in the LAUs is higher than the 30 percent threshold. Wildfires account for the majority of unsuitable habitat in
these LAUs (Forest Service 2018a). Current and historic status of lynx in Idaho and the latest scientific literature predict rare occurrence of lynx in the PNF and BNF. In Idaho, the total population number is unknown, but is expected to be low. Surveys conducted in 2007 using the National Lynx Protocol detected lynx in the BNF but not the PNF. The National Lynx Detection Survey was conducted from 1999 to 2003 in forests with potential to have lynx, including the BNF. A survey grid was established in the Cascade Ranger District in the Burntlog and Yellowpine LAUs from 2001 to 2003. No lynx were detected during those efforts (Forest Service 2018a).

Although there are no corridors or transition habitat in the SGP area, the Forest Service has drafted “lynx linkage areas” because of the importance of habitat connectivity for forest carnivores (Claar et al. 2004). As defined by Claar et al. (2004), lynx linkage areas are, “Habitat that provides landscape connectivity between blocks of lynx habitat. Linkage areas occur both within and between geographic areas where blocks of lynx habitat are separated by intervening areas of non-lynx habitat such as basins, valleys, agricultural lands, or where lynx habitat naturally narrows between blocks. Connectivity provided by linkage areas can be degraded or severed by human infrastructure such as high-use highways, subdivisions or other developments.” Linkage areas for Canada lynx have been estimated to occur North to South across Warm Lake Road (CR 10-579) and East to West across the SFSR (and likely also Johnson Creek Road (CR-10-413), the Stibnite Road portion of the McCall-Stibnite Road (CR 50-412), and the Burnt Log Road (FR 447).

The few historical observations on the BNF Cascade Ranger District indicate that Canada lynx can occur on the PNF and BNF. However, the Forest Service conducted lynx detection surveys on the BNF Cascade Ranger District between 2001 and 2003 (Forest Service 2001, 2002, 2003b), and no Canada lynx were detected during these hair snag/DNA surveys. The closest confirmed lynx detection resulting from formal surveys from the National Survey Grid was on the Lowman Ranger District (BNF) in 1999, approximately 60 miles south of the Village of Yellow Pine area. The lack of lynx detections from the large body of hair snag and remote camera survey work, both in the Canada lynx analysis area and in the larger context of the surrounding ranger districts, suggests Canada lynx is rare in the PNF and BNF, and detections would be more likely to result from a dispersing individual rather than a resident (Forest Service 2018a). Although lynx denning habitat exists on the BNF and is predicted to exist in the future across the PNF, there are no verified lynx dens or confirmed evidence of breeding. At present, occurrence of lynx in the Canada lynx analysis area is speculative.

**Northern Idaho Ground Squirrel**

In 2012, NIDGS was identified as a distinct species (Hoisington-Lopez et al. 2012). NIDGS is now recognized as *Urocitellus brumneus*, while its former subspecies, southern Idaho ground squirrel, is recognized as *Urocitellus endemicus*. The USFWS revised the taxonomy of the species under ESA rulemaking in Federal Register (80 Federal Register 35860).

NIDGS was listed as a threatened species under the ESA, as amended (61 Federal Register 7596). The Final Rule for this listing (65 Federal Register 17779) is dated April 5, 2000. The Recovery Plan for the Northern Idaho Ground Squirrel (Recovery Plan) was completed in 2003 (USFWS 2003). The plan summarizes objectives, criteria, and strategies for recovery of the species. The goal of the Recovery Plan is to increase population size and establish a sufficient number of viable metapopulations so that the
species can be delisted. The number of metapopulations considered to be sufficient for recovery is identified as 10, with each consisting of more than 500 individuals for 5 consecutive years.

A 5-year review of the current ESA classification for NIDGS was completed in 2017 (81 Federal Register 7571-7573). Although numerous conservation actions have been implemented or scheduled by the Forest Service, IDFG, and USGS since the last 5-year review, the recent review determined that the threats identified in the previous status review remained the same, particularly the primary threat of loss of suitable habitat, resulting from meadow invasion by conifers. Development of private lands within their limited range also continues to be a threat. The USFWS has initiated the Recovery Planning and Implementation process for NIDGS.

NIDGS are rare, endemic (i.e., native and restricted to a certain area), small mammals whose current known distribution is limited to a disjunct population in an approximately 2,965-acre area of Valley County and another larger, approximately 265,143-acre, area in Adams County in west-central Idaho. It has one of the smallest ranges of all North American land mammals. In this range, NIDGS occur at approximately 60 sites with an elevation range of 3,445 to 7,546 feet above mean sea level. Occupied sites are variable in size (2.5 to greater than 247 acres) and squirrel density (Wagner and Evans-Mack 2017). Typical habitat includes dry montane meadows or open scablands surrounded by ponderosa pine or Douglas-fir forest (Suronen and Newingham 2013). In March or April, squirrels emerge from their underground burrows to mate and begin their brief aboveground activity period (Yensen 1991). Hibernation starts again in July or early August (Goldberg et al. 2017).

Approximately 2,042 acres of occupied habitat and 60,450 acres of modeled NIDGS habitat occur on the PNF. The largest amount of both habitat types occurs in the Brownlee Watershed in close proximity to Bear, Idaho, which is well north and west of the NIDGS analysis area for the SGP. IDFG monitoring data from 2017 documented 308 individuals at 29 colony sites on PNF lands. Within the HUC 12 wildlife analysis area, there are approximately 17,917 acres of modeled suitable habitat (Figure 3.13-3).

The closest occupied site is located south of Cascade (Wagner and Evans-Mack 2017). In 2018, a survey was conducted in the modeled habitat in Scott Valley (June 19 to July 16) and along the Idaho Power Company transmission line alignment in Trout Creek (July 10 to July 12) (Yensen and Tarifa 2018), and private lands where access was obtained (between June 4 to July 17, 2019) (Yensen and Tarifa 2019). Over the entire geographic extent of 2018 and 2019 surveys, which cover almost the entire disturbance footprint for the SGP, there were no observations of NIDGS or signs of activity. However, during the surveys, areas with moderate to highly suitable habitat were identified for future surveys (Yensen and Tarifa 2018, 2019). Several of the large areas of highly suitable habitat include polygons 18136 at the Cascade Switching Station, 17378, 17379, and 17401 near the SGLF and Scott Valley Substation, 18084 and 18299 east of the Cascade Switching Station, and 17383 and 17211 north of the Cascade Switching Station (Yensen 2019). These areas are shown in more detail on Figure 3.13-3. NIDGS did occur historically in the Warm Lake area but limited surveys have been conducted (Yensen and Tarifa 2019). Although no NIDGS or signs of their activity were observed at sites during the surveys, there is a small possibility that NIDGS may occur in the future at suitable sites. Site checks and formal surveys would be conducted, as needed, prior to ground-disturbing activities in suitable habitat.
**Wolverine**

In February 2013, the USFWS published a proposed rule to list the DPS of the North American wolverine in the contiguous U.S. as a threatened species, citing the primary threat to the species as loss of habitat and range as a result of climate change (USFWS 2013; 78 Federal Register 7863). This decision was subsequently withdrawn. On April 4, 2016, the U.S. District Court of Montana vacated the USFWS’s withdrawal of its Proposed Rule (Case 9:14-CV-00246-DLC, Document 108; 81 Federal Register 71670). At the time of the initial DEIS publication in August 2020 for this Project, the proposed listing was under review and pending a final decision on the status of the species by the USFWS. Therefore, the Forest Service was directed to analyze the species as “proposed-threatened.” Additionally, because wolverines were a proposed species, rather than listed, there was no Critical Habitat designated for the species. On October 8, 2020, the USFWS determined that the best available science showed that the factors affecting wolverine populations are not as significant as believed in 2013 when the USFWS proposed to list the wolverine found in the contiguous U.S. as threatened. Therefore, this species did not meet the definition of threatened or endangered under the ESA and the USFWS withdrew its listing proposal. However, on May 26, 2022, the U.S. District Court of Montana vacated the USFWS’s 2020 decision to withdraw the 2013 proposed rule to list the wolverine as a threatened distinct population segment in the contiguous U.S. Therefore, for this analysis, the wolverine reverts back to its proposed for listing status (i.e., proposed-threatened) under the 2013 proposed rule.

The North American wolverine is the largest terrestrial member of the family Mustelidae (e.g., weasels, badgers, otters, ferrets, martens, minks, and wolverines, among others), with adult males weighing 26 to 40 pounds and adult females weighing 17 to 26 pounds (Banci 1994). Wolverines are opportunistic feeders, consuming a variety of foods depending on availability. They primarily scavenge carrion, but also prey on small animals and birds and eat fruits, berries, and insects (Banci 1994). They have an excellent sense of smell, enabling them to find food beneath deep snow, and can eat frozen meat and crush bones of large prey including deer, elk, and moose.

Wolverines are circumboreal (i.e., generally occurring throughout the northern portion of the northern hemisphere) in distribution, occurring in Europe, Asia, and North America. In western North America, the wolverine historically occurred in Alaska, Washington, Oregon, California, Nevada, Colorado, Utah, Montana, Wyoming, Idaho, and Canada. Wolverine habitat includes alpine tundra and all subalpine and montane forests (Wisdom et al. 2000). In the PNF and BNF, wolverines appear to strongly select for forest edges and concave landscapes, such as valleys. Wolverine distribution in Idaho is strongly correlated with snow, cold temperatures, high elevation montane habitats and rugged terrain, including talus slopes (Inman 2013). Spring snow cover (April 24 to May 15) is the best overall predictor of wolverine occupancy and appropriate levels of snow cover during the denning period is essential for successful wolverine reproduction. Wolverines have an extended mating period (from May to August) and give birth to kits in February to mid-March (IDFG 2014). Dens tend to be in areas of high structural diversity with logs and large woody debris, large boulders, and deep snow (Inman et al. 2007). Den sites are usually located amongst rocks or root wads, within hollow logs, under fallen trees, or in dense vegetation (IDFG 2014). Wolverine summer habitat in Idaho is associated with high-elevation whitebark pine communities with steep slopes and coarse talus (IDFG 2014). The wolverine analysis area includes suitable habitat for the wolverine. The largest amount of high-quality wolverine habitat exists in the SFSR watershed (approximately 231,659 acres), which includes areas adjacent to the FCRNRW.
Although new evidence suggests more social interaction, wolverines tend to be solitary and primarily nocturnal. They are active year-round and will travel during daylight hours. Wolverines have large spatial requirements, with home ranges varying in size depending on sex, age, availability of food, and differences in habitat (Banci 1994). Male and female home ranges in central Idaho are the largest reported for the species (Copeland 1996). A winter recreation study evaluated home range areas and estimated male minimum and maximum home range size at 154 and 833 square miles, respectively, with female ranges estimated from 49 to 162 square miles (Heinemeyer et al. 2017). Food availability and dispersion, spatial configurations of conspecifics (i.e., members of the same species), habitat, and topography also are suggested influences for wolverine home range selection and size (Banci 1994; Copeland 1996; Hornocker and Hash 1981). According to IDFG (2014), wolverines also are territorial, which influences their home ranges, typically reducing its overall size depending on prey availability and the local population of wolverines. While male and female ranges can overlap, males avoid other male territories and females avoid other female territories. This is important because territoriality constraints define how wolverines can react to changes in habitat quality or displacement from occupied habitat.

Wolverines naturally occur at low densities and have low reproductive rates. Wolverine populations in the Rocky Mountains are small (Schwartz et al. 2009). Although there are estimates for population carrying capacity in Idaho, there is currently no valid population estimate (IDFG 2014).

The SGP area is located within two Wolverine Priority Conservation Areas, Tier 1 Game Management Units (GMUs) 25 and 26, as defined by the Management Plan for Conservation of Wolverines in Idaho, 2014-2019 (IDFG 2014). Tier 1 are the highest scoring GMUs based on potential wolverine use, cumulative threats, and amount of unprotected habitat.

Historically, wolverines have been documented on the PNF and BNF within the wolverine analysis area (Table 3.13-3). As shown on Table 3.13-3 several of the observations include the same individuals. In 2010, the PNF, BNF, and Sawtooth National Forest collaborated with the Rocky Mountain Research Station, Round River Conservation Studies, IDFG, and other governmental and non-governmental organizations to assess wolverine populations and evaluate potential impacts to the species from winter recreation. The study was titled Wolverine-Winter Recreation Research Project: Investigating the Interactions Between Wolverines and Winter Recreation, and research efforts simultaneously and intensively monitored both wolverine and winter recreation use using global positioning system monitoring. The final report was released in December 2017 (Heinemeyer et al. 2017). The study results were updated in 2019 (Heinemeyer et al. 2019). Six years of trapping efforts (2010-2015) in the McCall study area confirmed 10 individual wolverines: six females (some of which were denning) and four males. The PNF and BNF contain known breeding habitat, and five den sites for four individuals (females) have been confirmed since 2010.

Modeled persistent spring snow cover was utilized (Heinemeyer et al. 2017) (Table 3.13-4) to describe existing habitat for wolverines. Persistent spring snow cover modeling results largely represent female breeding habitat, and therefore may not account for movements of wolverine at different times of the year within the wolverine analysis area, or their use of varying habitat types.

Figure 3.13-4 shows the distribution of persistent late spring (i.e., April 24 to May 15) snow cover in the wolverine analysis area as modeled for the northern hemisphere from 2009 through 2015 (Heinemeyer et al. 2017). The model uses the number of years (out of seven) in which snow cover was present in the spring in selected terrestrial pixels (very small, mapped areas).

This spring timeframe generally corresponds to the period of wolverine den abandonment. The overall wolverine analysis area includes a variety of habitats, including large areas that would typically not have persistent spring snow cover (i.e., Cascade Lake and Warm Lake Road). These are areas where wolverines are expected to travel through at different times of the year. Most dens and associated breeding habitat have been located in areas that were snow covered for 6 to 7 years. Hence, higher elevations on the eastern side of the wolverine analysis area are more likely to have persistent snow, and therefore higher quality habitat, in more years, compared to western portions of the wolverine analysis area. This has been confirmed by regular documentation of individuals using the area and predicted winter ranges based on global positioning system locations of collared animals.

**Monarch Butterfly**

The monarch butterfly is a candidate for listing under the ESA with a wide range across the U.S. (85 Federal Register 81813). In the west each spring, monarchs migrate to the north and east from coastal California toward the Rocky Mountains and Pacific Northwest (USFWS 2020a). This migration may span several generations of monarchs and the Project vicinity is considered part of the species’ summer breeding range. While seasonally occupying the area, monarchs often remain near water resources (particularly in arid climates) and are largely dependent on milkweed (*Asclepias spp.*) for reproduction. Western monarchs migrate back to coastal California each fall to overwinter. These populations overwinter in coastal groves of blue gum eucalyptus (*Eucalyptus globulus*), Monterey pine (*Pinus radiata*), and Monterey cypress (*Hesperocyparis macrocarpa*) (USFWS 2020a).

Range-wide, limited monitoring of the monarch butterfly began in the 1980’s, although large-scale yearly assessments did not begin until 1997. Since 1997, population counts have generally been declining every year (IDFG 2017a). The primary threats impacting monarchs are habitat loss and fragmentation, loss of milkweed, and intensified weather events that impact monarch populations. Surveys for the monarch butterfly have historically focused on locations of milkweed. Milkweed typically occurs in non-forested openings along waterways and may also occur in roadside ditches, agricultural fields, and pastures. Monarch and milkweed suitability models in Idaho show the predicted suitability for milkweed species and monarch butterflies on the PNF in the vicinity of the SGP to be low based on 36 variables such as soils, topography, climate, and distance to water (Svancara et al. 2019). Additional suitability models have also been published by the Xerces society (Xerces Society for Invertebrate Conservation 2018). Areas mapped as ‘Low Suitability’ are typically excluded from project analysis. Floral resources used by monarch butterflies for migration can occur in a broader range of habitats and are not restricted to non-forested vegetation along waterways.
Existing habitat for monarchs on the PNF occurs primarily on the Council and Weiser Ranger Districts, along waterways and where soils are wet, such as wet meadows and ditches. Monarchs only breed where milkweed is present, but they depend on the nectar from various floral resources during migration. It is suspected that monarch presence on the PNF is more closely associated with migration than with breeding, but more data collection and habitat assessment is needed.

While the entirety of the wildlife analysis area is within the species range, most milkweeds in Idaho are in the southern portion of the state between Boise and Twin Falls along the Snake River or in the panhandle portion of the state (Svancara et al. 2019). Surveys have not occurred in the wildlife analysis area for this species; however, according to the USFWS Monarch Conservation Database, only one acre of milkweed with 21 individual plants has been mapped in Valley County, Idaho where the Project occurs (USFWS 2020b). Therefore, while monarchs may occur in the wildlife analysis area, the probability is low.

3.13.4.3 Focal Species, including Region 4 Sensitive Species and Management indicator Species

Many of the focal species selected for analysis for the SGP also are Region 4 Sensitive species. Those species are designated by Forest Service Regional Foresters for specific regions or forests. There are 16 Regional Forester Sensitive Species (sensitive mammals, birds, and reptiles/amphibians) from the Intermountain Region (Region 4 of the Forest Service) included in this analysis (Table 3.13-1).

The following species (R4 Sensitive, MIS, focal species, or big game species) (Table 3.13-1) determined to have suitable habitat and documented occurrence or are assumed to occur in the wildlife analysis area are discussed below. Additional species considered but excluded from this analysis due to the wildlife analysis area being outside of the species range or lack of modeled habitat include Lazuli bunting, spotted bat, Harlequin duck, and yellow-billed cuckoo.

*Habitat Family 1 – Low-Elevation, Old Forest*

Family 1 includes wildlife species associated with low elevation, old forest vegetation types and has been identified as a habitat family of greatest conservation concern, due to widespread and substantial declines in habitat quantity across their range (Wisdom et al. 2000).

Family 1 wildlife species depend on single-story, and to a lesser extent, multi-story, lower elevation old forest stands as source habitats. Family 1 source habitat occurs in large tree, low canopy cover conditions in PVGs 1, 2, 3, and 5, and in those habitat types of PVG 6 where ponderosa pine is a major seral component. Special features of this source habitat are large-diameter live trees and snags (Wisdom et al. 2000). Historically, these habitat types were maintained in a relatively open condition by frequent, nonlethal fire.
White-headed woodpecker. The white-headed woodpecker is a regional endemic species of the Interior Northwest and may be particularly vulnerable to environmental change because it occurs in limited distribution, with narrow habitat requirements in dry conifer forests. The white-headed woodpecker is closely tied to mature ponderosa pine forests, with live and dead ponderosa pine trees greater than (> 20 inches dbh in open canopy conditions. The white-headed woodpeckers also require heterogeneous (i.e., mixed or varied) landscapes characterized by a mosaic of open- and closed-canopied ponderosa pine forest. Although white-headed woodpeckers have not been documented in the analysis area, they may pass through. They are expected to be uncommon and due to specific breeding habitat requirements, are not expected to breed and nest in the wildlife analysis area. The closest recorded observations are approximately 6 miles north and 16 miles west of the SGP (Forest Service 2017c).

On the PNF and BNF, vegetative communities that may provide source habitat conditions include PVGs 1, 2, 3, 5, and 6 (Nutt et al. 2010). While the drier habitat types in PVGs 3 and 6 can develop cover types with ponderosa pine in the larger size classes and open canopies, these conditions are not found as commonly as in PVGs 1, 2, and 5 across the PNF and BNF. Large diameter snags are an essential habitat feature for white-headed woodpecker. Current breeding habitat on the PNF is concentrated on the west side of the Forest, on the Council and New Meadows Ranger Districts. Approximately 5,070 acres of white-headed woodpecker modeled source habitat occurs in the wildlife analysis area (Table 3.13-5; Figure 3.13-8).

Lewis’s Woodpecker. The Lewis’s is closely associated with recent burns and responds favorably to stand-replacing fires (Tobalske 1997), whereas habitat for other Family 1 species is usually maintained by frequent, low-intensity burns that retain large and old-forest habitat. The Lewis’s woodpecker is characterized as a ‘burn specialist’ due to its preference for nesting within burned pine forests. Distribution is closely associated with open ponderosa pine forest in the western U.S. and fire-maintained old-growth ponderosa pine. Suitable habitat conditions include an open canopy, abundant arthropod (e.g., insects and spiders) prey, shrubby understory, and availability of nest cavities and perches. Approximately 4,141 acres of Lewis’s woodpecker modeled source habitat occurs in the wildlife analysis area (Table 3.13-5; Figure 3.13-9).

Cape Horn
Cape Horn (historical)
Species in Family 2 use late-seral, multi-, and single-layered stages of the montane community as source habitats (Wisdom et al. 2000). Source habitats for some species also include late-seral stages of the subalpine community or the lower montane community, or both. Source habitat for Family 2 overlaps Family 1; however, it encompasses a broader array of cover types and elevations (Wisdom et al. 2000). Family 2 source habitat occurs primarily in PVGs 3 through 11 (Forest Service 2003a, Appendix E), although some species use lower elevation types. Historical fire regimes in Family 2 vary by PVG but are dominated by mixed severity and lethal regimes (Forest Service 2003a, Appendix A).

Species that comprise Family 2 tend to be habitat generalists that use a wide range of conditions. Many are associated with both the large and medium tree size class forests in moderate- to high-stand canopy conditions. Some Family 2 species can take advantage of PVGs that exhibit uncharacteristically high tree densities and amounts of shade-tolerant tree species that have resulted from fire suppression and/or past management activities. As forest conditions increase in density and shade-tolerant species become more common throughout the landscape (either from suppression of fire or past vegetation management), the quantity and interconnectedness of Family 2 habitat increases.

**American (Northern) three-toed woodpecker.** The American three-toed woodpecker uses mature to old-growth, recently burned forests, and areas affected by pine bark beetles (Wiggins 2004). Saab et al. (2018) observed that the American three-toed woodpecker diet can consist almost entirely of spruce beetles, and they feed under the bark of freshly killed Engelmann spruce. The three-toed woodpecker is associated with disturbance events such as mountain pine beetle infestations and wildfire events that create areas with high densities of snags and insect prey (Wisdom et al. 2000). Three-toed woodpecker populations typically peak during the first 3 to 5 years after a fire.

Three-toed woodpeckers can utilize some forested conditions that are not within the historical range of variability (HRV) under PVGs 5 and 11. These conditions generally consist of higher tree densities and more complex vegetative structure than what would have developed when stands in these PVGs were experiencing historical disturbance processes. These dense conditions also would make stands more susceptible to insect infestations or stand-replacing wildfire important for disturbance-related species. For PVG 5, when functioning outside HRV, the Medium-High and High tree canopy cover class are included when in the Medium, Large, and Very Large tree size classes. For PVG 11, when functioning outside HRV, the High tree canopy cover class is included when in the Medium, Large, and Very Large tree size classes.

Although three-toed woodpeckers have not been recorded in the wildlife analysis area, and the closest observation in the Forest Service database is approximately 12 miles north of the wildlife analysis area (Forest Service 2017c), the habitat profile and burn history of the area could be attractive to the species, and it is likely they could occur. Approximately 21,675 acres of American three-toed woodpecker modeled source habitat occurs in the wildlife analysis area (Table 3.13-6; Figure 3.13-10).

**Black-backed woodpecker.** The black-backed woodpecker uses montane and boreal coniferous forests with standing snags. This species is associated with disturbance events such as mountain pine beetle infestations and wildfire that create areas with high densities of snags and insect prey (Wisdom et al.
They are strongly associated with recently burned forests (often colonizing them within one year after a fire) and excavate nests in snags (Saab et al. 2009).

On the PNF and BNF, vegetative communities that may provide source habitat conditions for black-backed woodpecker include PVGs 8, 9, 10, and 11 in the Medium and Large tree size classes and with moderate or high canopy cover (Nutt et al. 2010). PVG 5 also can provide source habitat when outside of the HRV. It is recommended that Medium (10 to 19.9 inches dbh), Large (20 to 29.9 inches dbh), and Very Large (>30 inches dbh) tree size classes be used to model source habitat for the black-backed woodpecker, both for within and outside the HRV. Mountain pine beetle infestations and/or high intensity fire events are primary recycling agents in these PVGs; both are disturbances associated with woodpecker habitat and population irruptions. Snags are a special habitat feature for woodpeckers and provide nesting and foraging opportunities. Approximately 49,424 acres of black-backed woodpecker modeled source habitat occurs in the analysis area (Table 3.13-6; Figure 3.13-11).

**Dusky grouse (summer).** Dusky grouse is a large grouse associated with mountain forest which contain ponderosa and lodgepole pine, aspen, and fir. This species is a forest dwelling grouse native to the Rocky Mountains, a permanent resident on the PNF and BNF, which moves to higher elevations in winter.

While herblands, grasslands, and shrublands (e.g., mountain mahogany, chokecherry, serviceberry, rose, bitterbrush, sagebrush) are commonly described as summer habitat, use of these habitats primarily occurs when they are within or adjacent to forested stands, typically within open ponderosa pine or Douglas fir habitat types (Wisdom et al. 2000). Wisdom et al. (2000) described dusky grouse summer source habitat as contrast habitat that occurs on the interface between forest and openings and generally at lower elevations than in winter. These openings, whether natural or created by harvest or fire, can develop an inter-mix of herb, shrub, and/or seedling vegetation that provides cover and forage for dusky grouse, and yet are still within the larger matrix of a later seral forest. This kind of mosaic commonly occurs in the lower range of tree canopy covers. Approximately 20,509 acres of dusky grouse modeled source habitat occurs in the analysis area (Table 3.13-6; Figure 3.13-12).

**Boreal owl.** The boreal owl requires mature conifer forests with moderate to high canopy cover and snags. This species is strongly associated with higher elevation subalpine fir/spruce-fir habitats (>5,000 feet elevation), where their dominant prey food, red-backed vole, is available. Boreal owls, as secondary cavity nesters, also are highly dependent on pileated woodpeckers and northern flickers for nest cavities. Association of foraging and nesting habitat, snags, and downed wood for nest sites and prey habitat, are special habitat features not represented by the model.

This species has been documented in the wildlife analysis area at higher elevations. The nesting/fledging period is April through July (IDFG 2012). The species has been documented, particularly in the mine site, village of Yellow Pine, and Landmark areas, and most likely breeds in the wildlife analysis area. Approximately 28,602 acres of modeled source habitat is present (Table 3.13-6; Figure 3.13-13).

**Fisher.** The fisher, a large member of the weasel family. The species was previously granted candidate species status by the USFWS for the West Coast DPS (68 Federal Register 41169; July 10, 2003), but listing was determined to be “not warranted” for the Rocky Mountain Region DPS (76 Federal Register 38504; June 30, 2011). The Forest Service has fisher survey units located across the PNF and BNF and the most recent state monitoring was conducted in 2018-2019 (IDFG 2019b). Although commercial harvest of fishers in Idaho has been closed for more than 60 years, fisher populations have not recovered in western portions of their range (Lofroth et al. 2010; USFWS 2010). On the PNF, incidental trapping continues to be a mortality issue for fisher.

In the western U.S., fishers use coniferous and mixed mature forests, often in riparian corridors and drainages (Meyer 2007; Raley et al. 2012). Sauder and Rachlow (2014; 2015) found that fisher core use areas were often composed of moderate amounts of high canopy cover forest and moderate landscape edge density, and that forest heterogeneity was an important factor in habitat selection. Olson et al. (2014) also found that the probability of fisher occurrence was highest in mesic (i.e., containing a moderate amount of moisture) forest types with tall trees (i.e., between 25 and 50 meters), high annual precipitation, and mid-range winter temperatures. This is supported by Schwartz et al. (2013), who found that fishers disproportionately used late successional forests with large diameter trees in their study in the Northern Rocky Mountain region. They den in cavities of dead snags, living trees, or in downed trees greater than 20 inches dbh (Meyer 2007). In conifer forests of Idaho, fishers have very large home ranges. Average home range size estimates are approximately 2,400 to 10,000 acres for females and 7,400 to 20,000 acres for males (Jones 1991; Olson et al. 2014).

Vegetative communities that may provide source habitat conditions include PVGs 3, 6, 8, 9, and 10 in medium and large tree size classes and moderate or high canopy cover classes (Nutt et al. 2010). Special habitat features include riparian corridors (travel, prey patches), down logs (resting and den sites), and snags (resting and den sites). Approximately 19,711 acres of modeled source habitat occurs in the wildlife analysis area (Table 3.13-6; Figure 3.13-14).

**Flammulated owl.** Flammulated owl, is a cavity nester that prefers stands of medium to large trees (ponderosa pine, Douglas-fir, and aspen) with moderate canopy closure (Forest Service 2012a). Occupied habitat is strongly associated with upper slopes (upper third) or ridges. This species is highly migratory and, as an insectivore, would only occur in the SGP area during warmer time periods when insects, particularly moths, are available. Breeding home ranges average approximately 35 acres. Nesting occurs in April and May, with fledging typically complete by the end of July (IDFG 2012). At higher elevations, this may fluctuate with prey availability.

Vegetative communities that provide source habitat conditions include PVGs 2, 3, 5, and 6 in the medium and large tree size classes and moderate canopy cover class (Nutt et al. 2010). Historical fire regimes in these PVGs include nonlethal and mixed (Forest Service 2003a, Appendix A). Snags are a special habitat feature for flammulated owls and provide nesting sites. Flammulated owl monitoring transects exist in the SGP area and the species has been documented and breeds in the wildlife analysis area. Approximately 18,321 acres of modeled source habitat is present (Table 3.13-6; Figure 3.13-15).

**Great gray owl.** Great gray owl source habitat includes old forests (multi- and single-story); unharvested, young, multi-story forests; and stand-initiation stages of subalpine and montane forests, including
Engelmann spruce, spruce-subalpine fir, and riparian woodlands (Wisdom et al. 2000). The habitat components considered most important for great gray owl are suitable nesting sites in mature or older forest, with adjacent suitable foraging areas in non-stocked and seedling forests, meadows, and open riparian habitats adjacent to extensive meadows. Large diameter trees or snags are special habitat features for the great gray owl. Great gray owls often use the nests of other raptor species in large, broken-topped trees and are known to nest within northern goshawk nest stands. Though associated with mature to old-growth conifer forests, they forage in open areas within 2 miles of nests, including meadows, bogs, and peatlands (Ulev 2007). Due to their close association with snow cover, breeding season typically lasts from late February to late May on the PNF and BNF.

Vegetative communities on the PNF and BNF capable of providing great gray owl source habitat conditions include PVGs 3, 6, 7, 8, 9, 10, and 11. Many of these PVGs historically had mixed and lethal fire regimes, which can create both open and forested habitats being used by the owls. The model likely greatly overestimates the amount of source habitat because it does not account for forest stands proximate to open meadows or other foraging habitats. Due to their specific habitat requirements, including this habitat mix, great gray owls are expected to be uncommon within the analysis area.

Great gray owls have limited Forest Service documentation in the wildlife analysis area. Strobilus Environmental (2017) indicates that great gray owls have been documented in the Warm Lake and Landmark LAUs. Broadcast surveys were conducted at two sites within the wildlife analysis area and no individual owls were detected (HDR 2017j and 2017k). Approximately 75,932 acres of modeled source habitat is present (Table 3.13-6; Figure 3.13-16).

**Northern goshawk.** The northern goshawk occupies northern conifer forests. Northern goshawks use a variety of forest ages, structural conditions, and successional stages (Griffith 1993), and are associated with shrubland and grassland habitats. The home range for a goshawk pair is up to 6,000 acres (Griffith 1993). Nesting is typically from April through June and fledging is generally complete by the end of August.

Goshawks have been documented at low levels in the wildlife analysis area, specifically in the Burntlog and Stibnite LAUs (Forest Service 2018a; Strobilus Environmental 2017); although there appears to be sufficient habitat for breeding, goshawks are expected to be uncommon. HDR conducted goshawk surveys in 2015 and 2017 in the proposed mine site area at the request of the Forest Service. No adult or juvenile goshawks were observed during broadcast acoustical surveys, and no evidence of nests, whitewash (i.e., urine and feces), prey remains, or molted feathers were observed (HDR 2015b, 2017k).

On both the PNF and BNF, source habitat for northern goshawks occurs in all PVGs except 1 and 11 in the medium and large tree size classes and moderate and high canopy cover class (Nutt et al. 2010). PVGs 2 through 9 are capable of developing multi-layered, mature, and late seral stands with a dense canopy. For some PVGs, such as PVG 6, these conditions occur under historical fire regimes, while other PVGs, such as PVGs 2 and 5, develop these conditions from fire suppression and altered fire regimes.

Approximately 45,758 acres of modeled source habitat is present in the wildlife analysis area (Table 3.13-6; Figure 3.13-17).

Cape Horn (historical)
Pileated woodpecker. Pileated woodpeckers serve a variety of functional roles within the community and are associated with habitat elements used by other species in this family. Pileated woodpeckers occupy dense deciduous, coniferous, or mixed forests; open woodlands; second growth forests; and parks and wooded residential areas of towns. The species prefers habitats with tall, closed canopies and high basal areas. General characteristics of habitat provide opportunities for nesting, roosting, and foraging and include the presence of large diameter trees and snags, multiple canopy layers, decaying wood on the forest floor, and a somewhat moist environment that promotes fungal decay, and ant, termite, and beetle populations to forage upon. Source habitats for pileated woodpeckers are typically late-seral stages of subalpine and montane community types. Home ranges average 1,006 acres.

On the PNF and BNF, vegetative communities that may provide source habitat conditions include PVGs 2, 3, 5, 6, 8, and 9 in the large tree size classes and moderate and high canopy cover class (Nutt et al. 2010). Some PVGs are capable of providing source habitat conditions under historical fire regimes while others do so because of altered fire regimes (i.e., PVGs 2 and 5). Special habitat features for pileated woodpecker include large diameter (>21 inches dbh) snags and hollow live trees for nesting and roosting, and large standing dead and downed trees for foraging. Some of these special habitat features are not well represented by the model. The very large tree size class is very limited in the analysis area. Approximately 1,722 acres of modeled source habitat is present in the wildlife analysis area (Table 3.13-6; Figure 3.13-18).

Silver-haired bat. Silver-haired bat is associated with primarily forested areas adjacent to lakes, ponds, and streams, including areas with human disturbance. They are generally migrant over a major part of their range. Summer roosts are in conifer/deciduous tree foliage, cavities, loose bark, and sometimes in buildings. Day roost trees are usually characterized as large (>21 inches dbh), dead or live with some defect, with loose bark and cracks. Winter habitat includes mines, caves, rock crevices, under tree bark and hollow trees / snags.

Source habitat for resident silver-haired bats is in forested and woodland areas, generally late seral stages of subalpine, montane, lower montane, and riparian woodland community groups. Modeling of source habitat for this species, which consists of both foraging and roosting habitat, utilizes Seedling (<4.5 feet tall), Medium (10 to 19.9 inches dbh), Large (20 to 29.9 inches dbh), and Very Large (>30 inches dbh) tree size classes. Literature also supports use of forested stands in the Low (10 to 19 percent), Low-Medium (20 to 29 percent), and Medium (30 to 44 percent) tree canopy cover classes for preferred PVGs within their HRV. Silver-haired bats have been documented on Forest Service lands in the wildlife analysis area and in the FCRNRW (IDFG 2017a; 2013). Approximately 57,719 acres of modeled source habitat is present in the wildlife analysis area (Table 3.13-6; Figure 3.13-19).

Habitat Family 3- Forest Mosaic

Species within this family tend to be habitat generalists in montane forests. Most species also use subalpine forests, lower montane forests, or riparian woodlands as source habitats. A few species use upland shrub and upland herb communities. Source habitat occurs across all PVGs and structural stages. Three TEPC or Sensitive wildlife species are within Family 3: Canada lynx (discussed in TEPC section), wolverine (discussed in TEPC section), and mountain quail.
Mountain quail. Mountain quail is closely associated with riparian habitats (Forest Service 2012a). Wisdom et al. (2000) describes forest habitat associations for this species as all forested vegetation stages, except stem exclusion (i.e., forest stage where young trees are rapidly competing and growing densely) in Interior Douglas-fir, Interior ponderosa pine, and Western larch cover types.

On the BNF and PNF, vegetative communities that may provide source habitat conditions for mountain quail include PVGs 1, 2, 4, 5, 7, and 11 (Nutt et al. 2010). Historical fire regimes are nonlethal in low elevation types (PVGs 1, 2, and 5) and “mixed1” or “mixed2” in other PVGs. Riparian shrubland is a special habitat feature. In the Interior Columbia Basin, mountain quail are usually found within 100 to 200 meters (328 to 656 feet) of a water source. The source habitat model utilizes Seedling (4.5 feet tall), Sapling (0.1 to 4.9 inches dbh), Small (5 to 9.9 inches dbh), Medium (10 to 19.9 inches dbh), Large (20 to 29.9 inches dbh), and Very Large (>30 inches dbh) tree size classes and selected forested stands in the Low (11 to 19 percent) and Low-Medium (20 to 29 percent) tree canopy cover classes.

Mountain quail are most often found in areas with high abundance of shrubs and the model also includes Very Low (10 to 20 percent) and Low (20 to 30 percent) canopy cover classes for the SHRUB existing vegetation type and Very Low (10 to 20 percent), Low (20 to 30 percent), and Moderate (30 to 40 percent) for the FOREST existing vegetation type to model non-forest source habitat. Although approximately 72,681 acres of mountain quail modeled source habitat occurs in the wildlife analysis area (Table 3.13-7; Figure 3.13-20), the nearest recorded observation is approximately 8 miles west of the northern portion of the analysis area (Forest Service 2017c) and species occurrence is expected to be rare.

Habitat Family 5 – Forest and Range Mosaic

Family 5 species use a broad range of forest, woodlands, and rangelands as source habitat (Wisdom et al. 2000). Source habitats occur in all PVGs and structural types, as well as woodland and non-forested types. Human disturbance and altered fire regimes are primary factors affecting some species (Wisdom et al. 2000). Species associated with Family 5 potentially in the wildlife analysis are: gray wolf, peregrine falcon, Rocky Mountain bighorn sheep, and Rocky Mountain elk. Of the four species, current habitat modeling is only available for Rocky Mountain bighorn sheep. Remaining species are addressed qualitatively.

Gray wolf. Gray wolves are a Region 4 Sensitive species and are federally listed in several western states, excluding Idaho. Gray wolves in the northern Rocky Mountain states (i.e., Idaho, Montana, and parts of Oregon, Washington, and Utah) were delisted by the USFWS in May 2011. They are habitat generalists with large pack territories of up to 150 square miles (Snyder 1991). Their range is related to availability of prey species, including deer, elk, and, less commonly, moose, bighorn sheep, and domestic stock. Gray wolves are well documented in the wildlife analysis area. Natural Resource Manager (NRM) WILDLIFE records verify occupancy in and around the wildlife analysis area and several packs are known to occur in the FCRNRWA. Garcia and Associates observed tracks during a 2013 winter field study (Forest Service 2017c; Garcia and Associates 2013; Strobilus Environmental 2017). Gray wolves have been observed in the mine site, specifically at the proposed tailings storage facility (in June 1998), main ore processing area (May 2000), and Yellow Pine pit (June 1997) locations. Perpetua staff and consultants have observed gray wolves multiple times during exploration activities in the analysis area (Strobilus Environmental 2017).

Peregrine falcon. Peregrines are cliff nesters, utilizing cliffs from 30 to 400 meters (98 to 1,312 feet) high. Habitat surrounding the cliffs may be variable, ranging from old forests to second growth and sagebrush steppe environments. Common features of nesting habitat include close proximity (1,312 to 2,953 feet) to water, abundant avian prey, and lack of human disturbance during the breeding season (Pagel 1995). Although greater distances may be traveled, peregrines usually hunt within 10 miles of their nests with 80 percent of foraging occurring within 1 mile.

On the PNF and BNF, vegetative communities that could provide source habitat conditions include all forest and non-forest vegetation types. Source habitat is typically located within 10 miles of suitable nesting cliffs. Peregrine falcons have been documented within the wildlife analysis area and nesting has been verified along Johnson Creek and East Fork SFSR since 2000 (Forest Service 2018a). Breeding territories also are documented in the FCRNRW area.

Rocky Mountain bighorn sheep. Human settlement of Idaho in the mid-1800s increased harvest of bighorn sheep and introduced domestic sheep, resulting in a major loss of the species. Disease transmission from domestic sheep to bighorn sheep has resulted in substantial die-offs dating back to the 1870s in the Salmon River Mountains (Smith 1954). Current estimates place bighorn sheep numbers at 10 percent or less of the historic population levels.

Bighorn sheep occupy rugged canyons, foothills, and mountainous terrain at elevations ranging from 1,450 to 10,500 feet and slopes of 45 percent or greater. Key habitat features include steep, rugged escape
terrain, such as cliffs and rockslides; grasses and forbs for forage; and a limited amount of tall vegetation. Wisdom et al. (2000) describes source habitats for bighorn sheep in alpine, subalpine, upland shrubland, and upland herbland community groups. Alpine and subalpine community groups are primarily summer range and upland herbland and shrubland are used in both seasons, depending on elevation (Wisdom et al. 2000).

NRM WILDLIFE has a record of one bighorn sheep on the eastern border of the Stibnite LAU (Forest Service 2017c). They are known to occur in the FCRNRW area, which includes lambing areas for the Big Creek herd and collaring data from the Forest Service. The IDFG (2017b) estimated the bighorn sheep population in the Middle Fork Salmon River Population Management Unit (PMU) to be about 477 individuals in 2017, which was a decrease from survey estimates in 2004, 2006, and 2009. In addition, one bighorn sheep was observed approximately 6 miles northeast of the mine site (Strobilus Environmental 2017).

Bighorn sheep occurrence on the PNF and BNF is concentrated in areas with preferred habitat features such as Hell’s Canyon National Recreation Area and the FCRNRW. Bighorn sheep have been documented in the wildlife analysis area. IDFG collaring data (2017b) verified several existing herds (Pinnacles, Big Creek, Monumental herds) and lambing areas within proximity to the SGP area. Approximately 59,405 acres of summer habitat and 10,306 acres of winter habitat is modeled within the wildlife analysis area, including some habitat on the Salmon-Challis National Forest.

On the PNF and BNF, PVGs 1, 2, 4, 5, 7, 9, 10, and 11 in all tree size classes and with a low canopy cover provide summer source habitat when this habitat is within 2 miles of rock, cliff, or talus slopes with greater than 27 percent gradient. Winter source habitat is composed of numerous sagebrush-dominated cover types when the canopy cover class is low, and these cover types are within 2 miles of rock, cliff, or talus slopes with greater than 27 percent gradient. More information on the PNF bighorn sheep model is available in the PNF Bighorn Sheep Supplemental EIS Technical Report, Source Habitat Model (Forest Service 2010d).

Table 3.13-7 and Figures 3.13-5 and 3.13-6 display modeled summer and winter bighorn sheep habitat occurring in the analysis area.

**Habitat Family 7 – Forests, Woodlands, and Sagebrush**

Species in Family 7 use a complex pattern of forest, woodlands, and sagebrush cover types (Wisdom et al. 2000). A distinguishing feature of the family is that most species have specialized requirements for nesting and roosting, which often limits population size and distribution. Two Region 4 Sensitive wildlife species are members of Family 7: spotted bat and Townsend’s big-eared bat. Due to the rarity of spotted bat, only Townsend’s is addressed qualitatively in this analysis. Another Sensitive species, silver-haired bat (Family 2), which is believed to occur and has suitable habitat in the analysis area, is utilized as a proxy for other bat species.

**Townsend’s big-eared bat.** Townsend’s big-eared bat is a Region 4 Sensitive species and Idaho SGCN (Tier 3), with suitable habitat within the wildlife analysis area. Ponderosa pine, Douglas fir, and grand fir stands are abundant in the analysis area and may be used as summer maternity roost sites. Townsend’s
big-eared bats also will readily use underground mine workings and adits for daytime roosting (Gruver and Keinath 2006). There are no documented occurrences or records of Townsend’s big-eared bat in the wildlife analysis area. The nearest observation is approximately 20 miles north near the Snowshoe Mine on Crooked Creek in Idaho County (in the company of multiple other bat species) according to the NRM WILDLIFE database (Forest Service 2017c). No Townsend’s big-eared bat colonies have been recorded in Valley County as of 1999 (Idaho Conservation Effort 1999). They also have been documented using openings in cliff walls along the Snake River Canyon (Hells Canyon), about 65 miles west of the analysis area (Strobilus Environmental 2017).

**Habitat Family 13 – Riverine Riparian and Wetland**

Source habitat for species in Family 13 occurs in conjunction with riverine riparian and wetland areas. Some species within the family also use non-riverine riparian and wetland habitats. Adjacent forests and woodlands provide nesting sites for some species. Three TEPC or Sensitive wildlife species are members of Family 13: bald eagle, Columbia spotted frog, and yellow-billed cuckoo. Yellow-billed cuckoo is not analyzed as described earlier in this section.

**Bald eagle.** The bald eagle is known to occur along riparian areas and in the vicinity of large waterbodies. The removal of the bald eagle from the Federal List of Endangered and Threatened Wildlife and Plants became effective August 9, 2007. However, the bald eagle is afforded some protections under the Bald and Golden Eagle Protection Act and the MBTA.

Two key habitats have been identified for bald eagles: nesting territory and wintering habitat. Nesting territories are typically associated with large rivers, lakes, reservoirs, or ponds that produce fish (Buehler 2000). Territories are used in successive years and may include more than one nest site. Bald eagles nest relatively close to water (1.25 miles) with suitable foraging opportunities (Buehler 2000). The majority of nest sites are located within one-half mile of a major stream or water body (USFWS 1986).

Wintering habitat also is typically associated with aquatic habitats with some open water for foraging (Buehler 2000). Winter habitat suitability is defined by food availability, the presence of roost sites that provide protection from inclement weather, and the absence of human disturbance (Buehler 2000). Winter food sources (e.g., fish, waterfowl, and ungulate carrion) and their availability varies across bald eagle winter range. Bald eagles scavenging on carcasses off highways are susceptible to motor-vehicle impact injuries. Bald eagles will tolerate some level of human activity in areas of high prey availability.

Key features of source habitat for the bald eagle include available food resources and suitable sites for nesting and roosting. These features can be correlated with watershed pathways used to assess the conditions of the watershed. The pathways that have relevance to the bald eagle include watershed condition, water quality, channel conditions and dynamics, and flow/hydrology.

In the wildlife analysis area, bald eagles have nested at Warm Lake since the early 2000s and they also forage in the lake, as well as in the SFSR (nest site last documented in 2008), and in the Johnson Creek area.

**Columbia spotted frog.** Columbia spotted frogs are aquatic and typically occur in or near permanent bodies of water, such as lakes, ponds, slow-moving streams, and marshes (Gomez 1994). The frogs
generally occur along the marshy edges of such sites where emergent vegetation (e.g., grasses, sedges, cattails) is fairly thick and where an ample amount of dead and decaying vegetation exists. Some occupied sites also may have a layer of algae or small vegetation (e.g., duckweed) on the surface of the water. During summer, they may travel away from breeding sites but are still typically associated with aquatic sites with vegetated margins (Gomez 1994). Given the elevation range of the species, occupied aquatic sites may be surrounded by a wide variety of terrestrial vegetation, including mixed coniferous and subalpine forests, grasslands, and shrub-steppe communities.

Patla and Keinath (2005) describe three seasonally occupied habitats: breeding, foraging, and over-wintering. Breeding sites are used for egg deposition and larval development. These sites consist of stagnant or slow-moving water with some shallow (3.9 to 7.9 inches deep) water available. Emergent vegetation (sedges) is usually present. Foraging habitat is used by all post-larval stages of frogs for prey acquisition. These sites can occur as ephemeral pools in forests and meadows; intermittent and perennial streams; edges of rivers, riparian zones, and lake margins; and marshes. Over-wintering sites provide wet, well-oxygenated habitat that is protected from freezing temperatures. While some sites may be suitable for all three habitats, in many areas, these sites are spatially separated, requiring frogs to migrate between sites within the course of a year.

Key features of source habitat for the Columbia spotted frog include the aquatic site itself, its banks and bank-side vegetation, and the conditions of the surrounding uplands. These features can be correlated with watershed pathways used to assess the conditions of the watershed. The pathways that have relevance to the Columbia spotted frog include watershed condition, water quality, channel conditions and dynamics, and flow/hydrology. No special habitat features have been identified for the Columbia spotted frog.

Individuals have been observed by the Forest Service in the riparian analysis area (Forest Service 2017c), and they were incidentally noted along the East Fork SFSR near the mine site during raptor surveys in spring and summer of 2017 (HDR 2017k). They also may occur in other potentially suitable habitat in the riparian analysis area, such as forested areas adjacent to wetlands which may be used as winter hibernacula.

### 3.13.4.4 Idaho Species of Greatest Conservation Need

In addition to the PNF and BNF sensitive species, SGCN identified for the State of Idaho that may occur in the SGP area also are considered. The SGCN in the Idaho Batholith Ecoregion are discussed in this section (IDFG 2017a, 2017c). Several species have already been assessed as TEPC species and focal species (including Forest Service Region 4 Sensitive and MIS) or are described in the migratory bird species section. The species not described elsewhere are listed in Table 3.13-8.

These SGCN were analyzed in different groups depending on the habitats they generally occupy.

**General Habitats** – SGCN analyzed in this group include common nighthawk, hoary bat, and little brown myotis. The general wildlife analysis area was used for these species given their occupancy across several different habitats.
**Riparian Species** – SGCN analyzed in this group include western toad, western grebe, Clark’s grebe, and sandhill crane. The riparian analysis area was used for these species due to their habitat requirements.

**Alpine Species** – The only SGCN analyzed in this group is the hoary marmot. This species uses subalpine and alpine areas, which overlap much of the wolverine analysis area. While the marmot has a much smaller home range compared to the wolverine, the wolverine analysis area is used for this species because of the overlap in habitat types.

**3.13.4.5 Big Game Species**

Big game species that are expected to be present and have habitat in the wildlife analysis area include Rocky Mountain elk and mule deer (*Odocoileus hemionus*) (Forest Service 2003a, 2010a). These big game species have been recorded in the PNF and/or BNF and also in the wildlife analysis area (Strobilus Environmental 2017). The Atlas of Idaho’s Wildlife shows habitat present in the wildlife analysis area for these two species (IDFG 1997).

Roadless areas are often used for wildlife migration corridors (Forest Service 2007b). Big game species also may use these remote places for calving, escape cover, summer/winter ranges, or migrations between summer and winter ranges. While there are no corridors or transition habitat in the wildlife analysis area (Forest Service 2017d), big game migration routes and transition habitat might occur in the wildlife analysis area, but studies have not been conducted yet to map these big game habitats. Big game species can be legally hunted and are managed by the IDFG. The wildlife analysis area occurs in IDFG Big Game Management Units (BGMUs) 24, 25, 26, and 27.

**Rocky Mountain elk.** Rocky Mountain elk are a priority species/big game species of special interest in the PNF and BNF and are found in a variety of habitats. They are habitat generalists and have been repeatedly observed in and near the wildlife analysis area. The wildlife analysis area near the mine site includes elk winter habitat and predicted elk summer habitat, which could include calving areas.

Habitat use and distribution changes seasonally for this species and can be generalized by seasonal movements. During the winter, snow forces elk to move to lower elevation winter ranges. Winter ranges are often of mixed land ownership and include portions of the PNF and BNF, as well as other public and private lands. As snow recedes, elk follow the spring green-up back to mid- and high-elevation summer ranges located in the PNF (Forest Service 2017d).

IDFG monitors and manages elk at the zone level (i.e., aggregations of several BGMUs). The wildlife analysis area is located in BGMUs that are currently meeting the IDFG bull and cow elk population objectives (IDFG 2017c). BGMUs 24 and 25 are both located in the McCall Elk Zone (the portion of Valley County in the drainage of the SFSR south of the Hall Creek drainage on the east side of the river, and south of the Bear Creek drainage on the west side of the river, except that portion of the Secesh River drainage upstream from and including Paradise Creek drainage). BGMUs 26 and 27 are in the Middle Fork Elk Zone, and are northeast and southeast of the mine site, respectively. In surrounding elk zones that are below objectives, the IDFG is attempting to “increase the populations by reducing or eliminating cow harvest, adjusting bull harvest, and intensively managing predators to reduce the impacts of predation on those herds” (IDFG 2014b, 2017c). In a 2014 survey, IDFG (2018a) estimated a population of 816
individuals in BGMU 25, which was a 41 percent increase from the 2010 survey. No survey data were available for BGMU 24. As of the 2014 survey, the population was estimated to be 5,800 individuals in the McCall Elk Zone (Forest Service 2019c).

Source: IDFG 2017a; PNF/BNF Monitoring Data (Galloway 2019).

**Mule deer.** Mule deer are a priority species/big game species of special interest in the PNF and BNF. Mule deer are habitat generalists and have been observed frequently in and near the wildlife analysis area. There is no designated mule deer winter range in the wildlife analysis area. Mule deer are best adapted to seral, transitional habitat types.
IDFG manages and monitors mule deer at the BGMU level. Portions of the wildlife analysis area are in legal mule deer hunting units, including BGMUs 24, 25, 26, and 27. The IDFG (2018b) estimated the mule deer population in the Weiser-McCall PMU 2 (which includes BGMU 24) to be 35,269 individuals in 2010. The population estimate for the Middle Fork PMU 3 (includes BGMU 25, 26, and 27) was 10,248 individuals in 2010 (IDFG 2018b). In 2017, the estimated abundance of mule deer was 1,279 individuals in BGMU 25, 1,319 individuals in BGMU 26, and 6,007 individuals in BGMU 27 (Forest Service 2019c).

### 3.13.4.6 Migratory Bird Species, Bald and Golden Eagles

Migratory birds are protected under the MBTA, and bald and golden eagles also are protected under the BGEPA. Most of the bird species discussed in the sections above are protected by the MBTA, with the exception of the mountain quail and dusky (blue) grouse. The Idaho Partners in Flight (PIF) Idaho Bird Conservation Plan (Ritter 2000) was used to identify migratory bird species and habitats in the wildlife analysis area. The Idaho Bird Conservation Plan takes a habitat-based approach to conserving bird populations in Idaho and correlated priority bird species with four habitats of highest priority (Ritter 2000). Idaho PIF priority migratory bird species are shown in Table 3.13-9, including the high priority habitats they represent. Two of the four high priority habitats occur in the wildlife analysis area and are shown in Table 3.13-9.

#### Table 3.13-9 Migratory Bird Species and Priority Habitats in Wildlife Analysis Area

<td>Blue Grouse; Mountain Quail; Calliope Hummingbird; Willow Flycatcher; American Dipper</td>
</tr>
</tbody>
</table>

Migratory bird species known to occur in the wildlife analysis area through sightings or sign (e.g., nests, calls) include the golden eagle, Steller’s jay, gray jay, Clark’s nutcracker, common raven, and American dipper. Migratory bird species not documented, but assumed to occur due to suitable habitat, include the American robin, hermit thrush, Swainson’s thrush, varied thrush, and red-tailed hawk.

The USFWS lists bird species of conservation concern for bird conservation regions across the U.S. (2008b). These are species that have reduced populations or loss of essential habitat.
Table 3.13-10 lists these species for Region 10 of the USFWS; all also are protected under the MBTA. The species in this section include species of conservation concern other than the special status species previously described.

Six of the 17 bird species of conservation concern listed in Table 3.13-10 have a reasonable possibility of occurrence in the general wildlife analysis area: the calliope hummingbird, Lewis’s woodpecker, olive-sided flycatcher, willow flycatcher, Cassin’s finch, and Brewer’s sparrow.

### 3.14 Timber Resources

#### 3.14.1 Introduction

Timber resources are the trees used to develop merchantable forest products. Forest products include timber products, such as lumber, paper, and firewood, and other “special forest products,” such as floral greenery, Christmas trees, medicinal herbs, fungi, and other natural products (Forest Service 2017e). Timber resources in the SGP area consist of conifer tree species typically harvested to make forest products, including merchantable sawtimber-sized trees and sub-merchantable small trees.
3.14.2 Timber Resources Area of Analysis

The analysis area for timber resources encompasses the area containing saleable timber resources in which disturbance from any action alternative would occur (i.e., the area proposed for direct removal of timber). The extent of the analysis area for timber resources is more focused than the entire SGP area because large portions of the SGP area do not contain timber resources. Areas lacking timber resources include areas that have experienced wildfire in the past 20 years, areas beneath the existing transmission line, and existing roads. The analysis area includes NFS, private, and state lands, and lands managed by the BOR. NFS lands in the analysis area include portions of PNF) and portions of BNF. The analysis area for timber resources is shown on Figure 3.14-1. Some timber resource information is shown to extend beyond the boundaries of the analysis area in order to provide the reader with broader context for timber resources (i.e., the extent of private and state lands in the vicinity of the analysis area).

3.14.3.1 National Forest Management Act of 1976

National Forest Management Act of 1976: The NFMA of 1976 requires the Secretary of Agriculture to assess forest lands, develop a management program based on multiple-use, sustained-yield principles, and implement a resource management plan for each unit of the NFS. The NFMA, as amended, and its implementing regulations under 36 CFR 219, consolidate and articulate Forest Service management responsibilities for lands and resources of the NFS. The land and resource management plans developed for the PNF and BNF under NFMA and its implementing regulations, their relevant timber resource provisions, and the SGP-specific plan amendments that may be required for the SGP are summarized below.

The NFMA provides that, in developing land and resource management plans, the Forest Service is to identify lands that are not suited for timber production and assure that “except for salvage sales or sales to protect other multiple-use values, no timber harvest shall occur on such lands for a period of 10 years” (Suitability for Timber Production [16 USC 1604(k)]). NFMA and its implementing regulations include requirements to periodically re-verify the location of lands that are suited for timber production at least once every 10 years. Suited lands include forested lands outside withdrawn areas, such as designated wilderness areas, lands where reforestation can be assured, and lands where timber management activities can take place without causing irreversible resource damage to soil productivity or watershed conditions (16 USC 160). Further, the NFMA states, “it is the policy of the Congress that all forested lands in the NFS shall be maintained in appropriate forest cover with species of trees, degree of stocking, rate of growth, and conditions of stand designed to secure the maximum benefits of multiple use sustained yield management in accordance with land management plans” (Reforestation [16 USC 1604(d)(1)]).

Lands suited for timber removal are evaluated to determine the range of Forest Service commercial timber sale harvest levels. The quantity of sawtimber that may be sold from the lands suited for timber on a forest is expressed as Allowable Sale Quantity (ASQ), which represents the average annual maximum volume that a forest may sell during each decade. Generally, all timber sold and harvested on suited lands during a decade must be counted against the ASQ to ensure that no more timber than allowed is removed from the suited lands. ASQ is measured in board feet and is estimated during harvest.

Figure 3.14-1
Analysis Area for Timber Resources
Stibnite Gold Project
Stibnite, ID
The Multiple Use Act of 1955 (69 Statute 367, 30 USC 612): This Act provides for more restricted
surface use rights for unpatented mining claims located in 1955 or later than those located prior to 1955.
There are no unpatented mining claims within the SGP area that predate the 1955 Act (Midas Gold
2017g). FSM 2800, Minerals and Geology, Chapter 2810 Mining Claims clarifies timber ownership rights
on unpatented mining claims. Section 2813.13b–Claims Validated Subsequent to Act of 1955: Such
claims which otherwise come under 30 USC 612 carry the same surface rights as those described in
Section 2812, except for the following modifications:

- Right to occupancy and use necessary for prospecting, mining, and processing, but not the
exclusive right to the surface. Lands containing such claims are subject to the rights of the U.S. to
manage and dispose of the vegetative resources, to manage other resources except locatable
minerals, and to the right of the U.S., its permittees and licensees, to use so much of the surface
area necessary for such purposes and for access to adjacent lands.

- Right to cut timber on the claim for mining uses and for necessary clearing, except that timber cut
in the process of necessary clearing cannot be sold by the claimant. The U.S. has the right to
dispose of timber and other vegetative resources.”

As per statutory authority provided to the Forest Service by the Multiple-use Mining Act of 1955, the
Forest Service maintains rights to timber and other vegetation resources on all unpatented claims made
after 1955. For timber harvest on these lands, the Claimant must coordinate with the Forest Timber Staff
well in advance (ideally 1.5 to 2 years before the need to have the trees/timber removed from the subject
area).

Forest Service Handbooks and Manuals: The Forest Service has regulations and policies in FSHs
(1909.60 and 2409.17) and FSMs (1920, 2430, 2470, 2471, and 2472) related to forest vegetation (Forest
Service 2018b). Cutting and removal of merchantable trees from NFS lands must be consistent with
Forest Service directives, particularly FSM 2400, FSM 2800, associated regulations (36 CFR 223.9, 36
CFR 223.14), and FSHs (2409.17 and 2409.26), both of which detail silvicultural activities permitted on
government-owned land in the NFS.

Idaho Forest Practices Act: Administered by the IDL, this Act was enacted in 1974 to promote active
forest management and ensure that the health of forest soil, water, vegetation, wildlife, and aquatic habitat
is maintained during the growing and harvesting of forest trees in Idaho. The Idaho Forest Practices Act
requires forest practices rules for state and private lands to protect, maintain, and enhance natural
resources. To deliver timber to a mill, a timber harvest must file a “notification of Compliance” with the
IDL, indicating an intention to follow the rules pertaining to the Idaho Forest Practices Act and follow fire
hazard prevention measures of the IDAPA/Idaho Administrative Code 20.02.01. Notable rules include
requirements related to restocking, stream protection, logging operations, and soil protection (IDL 2018).

The Idaho Mined Land Reclamation Act (1971): The IDL also administers the Idaho Mined Land
Reclamation Act, which requires reclamation of affected lands to a productive condition, including both
lands affected by surface mining and the surface effects of underground mining. Incorporated into state
statute under Title 47 “Mines and Mining,” Chapter 15 “Mined Land Reclamation,” the law includes
procedures for reclamation that include plugging drill holes, and cross-ditching abandoned roads to avoid
erosion (Section 47-1509); and for vegetation planting that specify an operator shall plant vegetation species on affected lands “that can be expected to result in vegetation comparable to the vegetation that was growing on the area occupied by the affected lands prior to exploration and mine operations” (Section 47-1510) (IDL 2019).

The Valley County Comprehensive Plan: This comprehensive plan includes goals and objectives for the management and use of resources in Valley County, including natural resources such as timber. Goal I for “Economic Development” is “to promote and encourage activities which will maintain a strong, diversified economy.” Objectives under this Goal include “maintain the important role of the timber industry, tourism, outdoor recreation, mining and agriculture in the local economy and “Support ‘multiple use’ of public lands.” Goal IV for Natural Resources is “to maintain sustainable commercial harvesting and use of renewable timber land resources.” Goal V for Natural Resources is “to assure mining remains a viable element in Valley County’s economy.” Timber receipts as a source of revenue for the county has ceased and declines in the timber industry have created a hardship for the county as timber receipts played an important role in funding county schools and roads (Valley County 2018a).

The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for timber and include various objectives, guidelines, and standards for this purpose. To achieve the desired outcomes and conditions for both land stewardship and public service (i.e., desired conditions), the forest plans include management standards for timber resources at three scales: forest-wide level, more specific and focused MA level, and MPC level.

Generally, the desired conditions for timber resources are conditions in which a forest meets its timber sale program ASQ goals while managing lands suited for timber harvest in conformance with forest plan goals and strategies. Both forest plans evaluate available forestland within their respective boundaries to determine suitability for timber production and reflect the results of that evaluation by demarcating MPCs that allow timber harvest within areas containing suited acres. Despite the presence of timber species, if land is determined to be physically unsuited for timber production because of the inability to ensure adequate restocking or the potential for irreversible damage to soils or watersheds, timber production is removed as an intended use of that land. However, some exceptions for the removal of timber resources on unsuited lands are explicitly noted. In PNF MA 13, MPCs 3.1, 3.2, and 4.1c are identified as not suited for timber production; however, the Payette Forest Plan states that on these lands forest vegetation management actions, which include removal of timber resources, may be undertaken to “support the achievement of desired conditions or other resource objectives” consistent with the management goals laid out for them (Forest Service 2003a).

3.14.4 Affected Environment

Timberland vegetation in central Idaho is dynamic, with changes occurring through both natural processes and timber management practices, and therefore the distribution and composition of timber resources also are dynamic. Natural disturbance processes include fires, windstorms, landslides, and insect and disease outbreaks. Management of timber forest vegetation includes timber harvest, planting, thinning, and other timber stand improvement activities, as well as prescribed burning. This section describes the existing conditions for timber resources in the analysis area, including timber and special forest products. This
summary is based on best available vegetation and timber ownership information from the Forest Service and USGS as of August 2019.

### 3.14.4.1 Timber Vegetation

As described in **Section 3.10**, the Forest Service maps existing vegetation communities and updates their maps periodically; however, these data are only available for NFS land. The existing Forest Service vegetation mapping system, VCMQI, reflects the forest-specific dominance type phases found on NFS land and was used to describe seral-stage timber resource composition in forested areas on NFS lands in the analysis area.

Private, state, and other federal lands in the analysis area, that are outside the boundaries of the PNF or BNF, are not characterized by Forest Service vegetation mapping, and therefore timber vegetation conditions were extrapolated from publicly available datasets and aerial imagery (Perpetua 2021a).

Existing vegetation communities in the analysis area include many developed and natural communities that generally are divided into broad lifeform-type categories. Fires, both natural and man-caused, have frequently occurred in the analysis area and surrounding forests, and much of the analysis area is currently mapped as burned herbaceous (grasses and forbs), burned sparsely vegetated, and burned forest shrubland. The lifeform type “Coniferous Forest” is defined as being dominated by conifer species and includes all the vegetation types that are dominated by timber species. In general, the existing Coniferous Forest vegetation communities are those typical of high mountain regions in Idaho and the inland northwestern U.S. The most common unburned, existing Coniferous Forest vegetation dominance types in the analysis area, which are used as a proxy for timberland vegetation in the absence of timber-specific mapping, are lodgepole pine forests, subalpine fir forests, Douglas-fir forests, Ponderosa pine forests, and Engelmann spruce forests (Forest Service 2014b, 2014c, 2016b, 2017b).

Timberland vegetation communities in and immediately adjacent to the analysis area are shown in **Figures 3.14-2a through 3.14-2d**. Although timber outside of the analysis area would not be affected by SGP activities, it is shown to provide a larger, landscape-wide context.

### 3.14.4.2 Timber Resources

Many conifer tree species that are commonly harvested for commercial use are found in the analysis area. Coniferous Forest communities dominated by these species, either in monotypic (single species) stands or multi-species stands, are considered to contain timber resources. Timber resources (both sawtimber and other tree-based forest products) include materials used to develop timber products as well as “special forest products.” Timber resources in the analysis area are derived from trees traditionally used for forest products and include the following merchantable species of conifers:

- Douglas-fir
- Engelmann spruce
- Lodgepole pine
- Ponderosa pine
The above list excludes pinyon, limber pine, juniper, and whitebark pine (federally proposed as a threatened species) because they typically are not harvested for sale in the PNF or BNF (Witt et al. 2012), and vegetation communities dominated by these species are not included in the analysis area. However, in the event individuals of these species or other non-timber conifer species are encountered during SGP implementation they would be processed as timber species and included in merchantable volumes.

Special forest products, which are derived from sub-merchantable trees, sold from the PNF and BNF include Christmas trees, transplants (e.g., trees, shrubs, or herbaceous plants), fuelwood, and posts and poles (Forest Service 2017e). Special forest products also are called non-convertible products because they are products that are not converted into board foot or cubic foot measure. The analysis area contains a mix of sawtimber and sub-merchantable trees, and while sawtimber is reported in volume of wood as well as acres within the analysis area, sub-merchantable trees or “special forest products” are reported in terms of the acres they occupy.

### 3.14.4.3 Timber Extent

To determine the extent of timber resources in the analysis area, existing spatial vegetation mapping data from various sources, were combined to create a single consistent coverage in GIS. Data used to determine the extent of timber resources were collected from a variety of sources, including existing vegetation geographic information system data from the PNF and BNF (Forest Service 2016b, 2017b), publicly available LANDFIRE vegetation classification data (USGS 2016a), land ownership data managed by the Bureau of Land Management (BLM) (2017), management prescription boundaries from the PNF and BNF, and mine claim data provided by Midas Gold. Once the vegetation community coverage dataset was complete, the subset of the data containing conifer-dominant vegetation communities was extracted, because it represents the potential timber resources in the analysis area. Areas that do not support timber resources—either because the timber was recently removed (i.e., burned in a fire within the last 20 years) or not realistically present (i.e., within existing roads and within the existing transmission line corridor) were then removed from the potential timber resources layer. The result provides the basis of the estimates of timber extent in the analysis area.

3.14.4.4 Timber Ownership

Timber resource ownership varies across the analysis area and determines the standards used to manage timber resources. Timber resources in the analysis area are found on land managed by the Forest Service, privately owned land, state-owned land, and land managed by the BOR (BLM 2017; Forest Service 2016b) (Table 3.14-1). NFS land in the analysis area includes unclaimed areas and unpatented claims, both of which contain timber resources. Timber on unclaimed areas and unpatented claims within NFS land is managed by the Forest Service subject to applicable claimant rights associated with unpatented claims. Timber on patented claims is considered “private,” like timber on other private lands in the analysis area. Timber that is managed by the Forest Service is subject to applicable Forest Service management directives, while private timber is not. Privately owned timber is subject to guidelines set by the State of Idaho as well as Valley County. Timber on state lands follow guidelines set by the State of Idaho for timber utilization.

Source: Forest Service 2003a, 2010a; Perpetua 2021a.

\(^1\)“Patented” refers to timber on patented claims, which is privately owned by the claimant; “unpatented” refers to unpatented claims. According to information provided by Midas Gold all of the SGP claims in the analysis area were staked after 1955 (Midas Gold 2017g) and therefore all timber on these lands is managed by the surface land management agency (not by the claimant); “Unclaimed” refers to acreage lacking claim information in the available data, and it is assumed to contain timber that is managed by the surface land management agency/owner.

\(^2\)Acres are based on the timber resources (excluding burned areas) in the analysis area, which consists of the combined footprints of the 2021 MMP and Johnson Creek Route Alternative.

\(^3\)“Percent of the Analysis Area” represents the portion of the analysis area covered by different land management entities and mining claim distinctions, calculated as a percent of the extent of the entire analysis area.
Forest Service Timber

On NFS lands, Forest Service commercial timber sale program harvest levels are set geographically and reported in volume (reported in thousand board feet [MBF]) of sawtimber allowed to be harvested for sale (Forest Service 2012b). Forest Plan direction for the forest wide ASQ, wood product extraction goals, and Total Sale Program Quantity (TSPQ) also are reported in MBF (Table 3.14-2). The Payette and Boise Forest Plans do not provide direction for an ASQ of special forest products on NFS lands. However, because areas occupied by sub-merchantable timber resources are considered timberland vegetation, the removal of sub-merchantable timber constitutes a removal of timberland resource area from future production.

¹ROD for the FEIS and Revised Land and Resource Management Plan (Revised Plan). McCall, ID. Table II-2, page II-30. (Forest Service 2003a).
²Boise Forest Plan 2003-2010 Integration. Lowman, ID. Table II-2, page II-31. (Forest Service 2010a).

As described in Section 3.14.3.1, the Payette Forest Plan and Boise Forest Plan divide their lands into MAs, which are further subdivided geographically to account for different intended uses of different landscape areas. The subdivisions, or MPCs, specify the intended uses of a landscape unit, including whether timber harvest is an allowable use. If timber harvest is intended in an MPC, the unit will include “suited timberland” acreage (Table 3.14-3). Timber vegetation in the analysis area is found in one MA in the PNF: MA 13–Big Creek/Stibnite; and four MAs in the BNF: MA 17–North Fork Payette, MA 19–Warm Lake, MA 20–Upper Johnson Creek, and MA 21–Lower Johnson Creek. In the PNF, timber resources in the analysis area fall into two MPCs, neither of which include timber harvest as an intended use: MPC 3.1–Passive Restoration and Maintenance of Aquatic, Terrestrial, and Hydrologic Resources; and MPC 3.2–Active Restoration and Maintenance of Aquatic, Terrestrial, and Hydrologic Resources. In the BNF, timber resources in the analysis area fall within portions of MPCs 3.1 and 3.2, as well as MPC 4.2–Roaded Recreation Emphasis, and MPC 5.1–Restoration and Maintenance Emphasis in Forested Landscape. MPCs 5.1 and 4.2 in the BNF contain suited timberlands; therefore, timber removal and sale are allowed under special conditions and may contribute towards the ASQ for the BNF. MPCs 3.1 and 3.2 in the BNF do not contain suited timberlands. Timber resources in the portion of the analysis area containing suited timberlands (MPC 5.1 and MPC 4.2) are shown in Figures 3.14-3a-c.

¹Acres designated as suited for timber production are based on reported acreages in the Payette Forest Plan and Boise Forest Plan.
²Acres of timber vegetation in the Management Areas are based upon vegetation mapping provided by the PNF and the BNF.

State, Other Federal, and Private Timber

Unlike Forest Service timber resources, there is no NFMA land and resource management plan guiding the location and amount of timber resources intended to be harvested from the remainder of the analysis area. The State of Idaho Forest Practices Act, which would guide timber harvest from commercial timberlands on the other federal, state-owned, and private portions of the analysis area, sets requirements for timber harvest planning, harvest operation, and reporting only (IDL 2018). The extent or presence of commercial timberlands in these other areas of the analysis area is not readily available information, and not considered significant or necessary for the analysis of the effects of the SGP.

3.15  Land Use and Land Management

3.15.1  Introduction

The analysis area for land use and land management includes the combined footprint of all potential components for the SGP including the Operations Area Boundary, the access routes, transmission line infrastructure, and off-site facilities. The analysis area and land status are shown in Figure 3.15-1. The SGP primarily consists of NFS lands on the PNF and the BNF with some private, state, and BOR lands also included. Land use in the analysis area consists of mining uses, utilities, roads, agriculture, residential, fisheries, timber, tribal, recreational, and special uses. The discussion of existing conditions provides a land use context for the collective SGP area that could be impacted by the action alternatives.
3.15.2 Land Use and Land Management Area of Analysis

The analysis area for land use and land management includes the combined footprint of all potential components for the SGP, including Operations Area Boundary, access and haul roads (proposed and existing), utility infrastructure (proposed and upgraded), and off-site facilities (Figure 2.4-1).

3.15.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to land use and management for the Proposed Action and Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to Land Use and Land Management.

1872 Mining Law (as amended): Statutory right to search for, develop, and extract mineral deposits on federal land open to mineral entry. 30 U.S.C. 22 et seq.

Organic Administration Act of 1897: Authorizes the establishment of National Forest Reserves to improve and protect the condition of forested areas of the U.S., and to provide a continuous supply of timber for the use and necessities of the public. The Act provides for lands that have been open for mineral entry and location under the mining laws to remain subject to such entry and location. 16 U.S.C. 473-475, 477-482, 551.

Mining and Minerals Policy Act: Established a national mining and minerals policy which confirms the national interest to foster and encourage private enterprise in the development of a stable domestic minerals industry and the orderly and economic development of domestic mineral resources.

Multiple Use Act of 1955: Mining claims patented prior to 1955 provide the owner the rights under FSM 2800. 30 U.S.C. 612.

Bureau of Reclamation: A use authorization is required in accordance with 43 CFR 429.3 for certain uses or activities on BOR land. The BOR is responsible for authorizing or modifying the transmission line ROW on their lands.

Wild and Scenic Rivers Act: Preserves certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition.

National Environmental Policy Act of 1969: Requires federal agencies to analyze the expected environmental impacts of the agency’s Proposed Action.

Payette Forest Plan (Forest Service 2003a) and Boise Forest Plan (Forest Service 2010a): Provide management prescriptions designed to realize goals for achieving desired condition for geologic resources and geotechnical hazards and include various objectives, guidelines, and standards for this purpose. All uses of NFS lands, improvements, and resources, except those provided for in the regulations governing
the sale and disposal of timber and other forest products (36 CFR 223), minerals (36 CFR 228), and range management, including the grazing of livestock (36 CFR 222), are designated “special uses” and must be approved by an authorized officer (Title 36 CFR 251.50[a]).

Revised Statute 2477: The public ROW on federal lands is administered per Revised Statute 2477. Revised Statute 2477 public ROWs are under the jurisdiction of Valley County. Though Revised Statute 2477 easements in the SGP area have been asserted by Valley County, none have been adjudicated.

Idaho Roadless Rule: Established federal management direction for designated Roadless Areas in the State of Idaho to protect their important characteristics. Locatable mining activities are not affected by the Rule. 36 C.F.R. 294 Subpart C; 36 C.F.R. 294.25(b).

Idaho Mined Land Reclamation Act: Surface and underground mining of minerals for ultimate or immediate sale, in either the natural or processed state, must have an approved reclamation plan. I.C. § 47-1501.

Valley County Comprehensive Plan: Aims to ensure mining remains a viable element in Valley County’s economy and to promote and encourage activities that will maintain a strong and diversified economy through maintaining the important role of the local timber industry, tourism, outdoor recreation, mining, and agriculture (Valley County 2018a). Per Valley County Code Table 3-A, Section 9-3-1(6)(c)(1), mineral extraction regulated by state or federal agencies is identified as a permitted industrial use. Other uses subject to a conditional use permit that could pertain to the SGP include extractive industry uses; public utility supply, transfer, ore relay facilities including administration; and warehousing of equipment and products. Valley County Code Section 9-5A-2 identifies standards for roads and driveways, specifying public roads to be designed and constructed in accordance with Title 10 of the Valley County Code and in accordance with “Construction Specifications and Standards for Roads and Streets in Valley County, Idaho” (Valley County 2018a).

City of Cascade Comprehensive Plan: Provides goals, objectives, and action items pertaining to land uses in the “area of city impact.” Goals and objectives to support development of energy services could be applicable to improvements in the existing transmission line corridor and/or widening of the ROW (City of Cascade 2018).

City of Donnelly Comprehensive Plan: Describes the desired future land use classifications, including zoning, in the “area of city impact.” Objectives and policies to support development of energy services could be applicable to improvements in the existing transmission line corridor and/or widening of the ROW (City of Donnelly 2011).

The Payette Lakes Supervisory Area of the Idaho Department of Lands: Has jurisdictional authority over exploration- and mining-related activities in its administrative area (IDAPA 20.03.02).
State Endowment Lands: The existing transmission line is authorized to IPCo, and a portion of this ROW intersects State Endowment Lands. The IDL is responsible for granting or modifying the transmission line ROW on state-owned lands, if required.

3.15.4 Affected Environment

This section discusses land use and land management specific to the analysis area. Existing land use and land management, including existing access roads, utilities, and off-site facilities, are shown in Figure 3.15-1.

3.15.4.1 Land Ownership and Status

The SGP is composed of lands administered by the Forest Service (the PNF Krassel Ranger District and BNF Cascade Ranger District), the State of Idaho, BOR, and private lands. Table 3.15-1 summarizes land ownership in the SGP area for all acres affected by each of the alternatives.

1 Approximately 14 acres of land listed under the PNF is administered by the PNF but is within the boundary of the Salmon-Challis National Forest. Does not account for 67 acres of temporary surface exploration pads and roads on Payette National Forest (see Chapter 2 acreage tables).
2 Subtotals may not add to totals due to rounding.

Patented and Unpatented Mining Claims

The analysis area includes both patented and unpatented mining claims in the PNF Krassel Ranger District and the BNF Cascade Ranger District. Affiliates of Perpetua own or control patented and unpatented mill site and lode claims in the Operations Area Boundary (Table 3.15-2). No land ownership has been conveyed for unpatented claims (Forest Service 2013a). Affiliates of Perpetua own the patented claims in the Operations Area Boundary except for approximately 21 acres of patented Cinnabar Claims for which Perpetua holds an option.

#### 3.15.4.2 Land Use

**Operations Area Boundary**

The proposed Operations Area Boundary contains approximately 14,221 acres (Table 3.15-3). Within the Operations Area Boundary, there are 1,418 acres of existing disturbance, located on private (458 acres), state (36 acres), and Forest Service (915 acres) land. The mine site currently contains pits, tailings, and development rock storage facilities from previous mining activities. Mining has occurred in three general locations: Hangar Flats, Yellow Pine, and West End, with additional areas of mining-related disturbance occurring throughout the Operations Area Boundary; however, prior to Perpetua acquiring and consolidating the patented mining claims, mine operations had ceased. Intermittent restoration activities have taken place in the past as funding became available to the Forest Service. EPA, Forest Service, IDL, and IDEQ have funded remediation activities at the mine site (Section 3.7).

<td>14,220.8</td>
</tr>
</tbody>
</table>

1 Approximately 22.5 acres of land listed under the PNF is administered by the PNF but is within the boundary of the Salmon-Challis National Forest.
Access Roads

There are three existing primary access routes to the Operations Area Boundary from Cascade or McCall: Johnson Creek, Lick Creek, and SFSR routes (Section 3.16). The Lick Creek Route and SFSR route would not be utilized by the SGP so are not discussed further here. Within the analysis area, the Johnson Creek Route and Burntlog Route would both utilize Warm Lake Road from SH 55. The road starts in Cascade at an intersection with SH 55 and continues eastward for approximately 35 miles, ending at Johnson Creek Road (CR 10-413) at Landmark. The Johnson Creek Route is the only existing access route located in the SGP analysis area and includes Johnson Creek Road (CR 10-413) and the Stibnite Road. Johnson Creek Road is approximately 25 miles long, and the Stibnite Road is another 14 miles between the village of Yellow Pine and the mine site. Burnt Log Road (FR 447) is an existing 20-mile road in the SGP area; however, it does not currently provide access to the Operations Area Boundary. The proposed Burntlog Route corridor includes the existing Burnt Log Road and undeveloped lands where the route would connect with Meadow Creek Lookout Road (FR 51290) and Thunder Mountain Road.

Utilities

The IPCo operates approximately 64 miles of existing transmission lines, including a 42-mile, 69-kilovolt electric transmission line, and a 21.5-mile, 12.5-kilovolt electric transmission line. IPCo operates existing electrical substations located at Oxbow Dam, Horseflat, Scott Valley, McCall, Lake Fork, Warm Lake, and Thunderbolt Tap.

Existing communication facilities include a microwave relay tower installed by Midas Gold Idaho, Inc. in 2013, located on private land atop Cinnabar Peak, a 9,000-foot peak east of the SGP.

Off-Site Facilities

There are no existing off-site facilities associated with the SGP within the analysis area. Perpetua currently maintains an administrative office in Donnelly, and a core logging and storage facility in Cascade.

Rights-of-Way And Easements

There are approximately 140 acres of existing road ROW and 493 acres of existing transmission line ROW, totaling approximately 633 acres of existing ROW in the SGP area (Table 3.15-4).

Current roads in the analysis area include Cabin Creek Road (FR 467), Warm Lake Road (CR 10-579), Johnson Creek Road (CR 10-413), Stibnite Road (CR 50-412), numerous other forest roads, and the existing transmission line access roads. The existing transmission line ROW crosses private lands, as well as lands administered by the BNF, the PNF, Bureau of Reclamation, and the IDL. Components of the SGP would intersect with numerous easements for road access, including a FRTA easement along the Johnson Creek Route. There is an additional easement for approximately one mile of an abandoned railroad that is adjacent to SH 55 between Cascade and Donnelly.
### Table 3.15-4 Acres of Existing Transmission Line ROWs in the Analysis Area

1 The analysis area for land use and land management includes the combined footprint of all proposed action alternative components for the SGP area. Alternative components include the proposed SGP, all associated mine support infrastructure, all access and haul roads (proposed and existing), all utility infrastructure (proposed and upgraded), and proposed off-site facilities.

2 Subtotals may not add to totals due to rounding.

### Other Land Uses

#### Agriculture

In Valley County, agricultural land uses are challenging due to a limited growing season, soil conditions, high water table, and occasional summer frosting. According to the 2017 Census of Agriculture, in Valley County 75 percent of farms were pastureland for livestock, 14 percent were woodland, 8 percent were cropland, and 3 percent other (USDA 2017). Agricultural lands offer potential for subdivision and second-home development. Agricultural lands are valued not only for production, but as open space (Valley County 2018a).

#### Residential

The closest community to the Operations Area Boundary is the village of Yellow Pine, approximately 14 miles (northwest). Cascade, Donnelly, and Warm Lake are other communities within the analysis area. The existing transmission line passes through the Thunder Mountain Estates subdivision approximately 1 mile east of Cascade. Residential land use types include homesite land, recreation land, rural residential tracts, rural residential subdivisions, other rural land, urban residential lots, common areas, condominiums or townhouses, and various improvements to residential uses and lands (Valley County 2018a).

#### Fisheries

Activities pertaining to fisheries recovery are considered a major land use in and near the analysis area and are applicable to waterbodies. Recovery plans focus on actions that contribute to land use and land management actions including maintaining, protecting, and restoring tributary habitat; improving passage through barrier removal; reducing sediment delivery to streams by improving roads, riparian communities, and rehabilitating mine sites; restoring connectivity of populations; and conducting research.
and monitoring to implement and evaluate recovery activities (Forest Service 2022i). **Section 3.12** includes additional information regarding fisheries.

**Timber**

Timber harvest on NFS lands is guided by Forest Service regulations. On state and private lands, timber resources could be harvested in a manner that is compliant with IDL regulations. Timber resources in the SGP area are found on NFS, private, state, and BOR land (**Section 3.14**). **Section 3.14** includes additional information regarding timber resources.

**Tribal Uses**

Regional tribes exercise off-reservation rights for traditional land uses such as fishing, hunting, and gathering on NFS lands (Forest Service 2022q). **Section 3.24** includes additional information regarding tribal treaty rights, interests, and concerns.

**Recreation and Special Uses**

Public lands in the analysis area are widely used for recreation purposes. This includes NFS and state lands, which collectively make up about 80 percent of lands in the SGP area. Recreation use occurs during all seasons in the form of motorized recreation (e.g., all-terrain vehicles, snowmobiles), hunting and fishing, hiking, camping, canoeing/kayaking/rafting, biking, cross-country skiing, and snowshoeing. Nearby recreational facilities include trailheads, campgrounds, lookouts/cabins, picnic areas, and dispersed recreation areas (Forest Service 2022m). **Section 3.19** includes additional information on current recreation uses in the SGP area.

### 3.16 Access and Transportation

#### 3.16.1 Introduction

This section presents a brief description of local and regional transportation systems existing on land, air, and water in the analysis area, including roads, rail, port, and airstrips. The section focuses mainly on the local and regional road transportation system and provides a discussion of the road system development history, existing roads and areas of motorized access in the analysis area, vehicle accident data, and current (2015-2017 and 2019) traffic volumes.

#### 3.16.2 Access and Transportation Area of Analysis

The analysis area for access and transportation encompasses the overall road system (**Figure 3.16-1**). The analysis area is dominated by unpaved roads, one state highway, and county roads.
Figure 3.16-1
Access and Transportation
Area of Analysis
Stibnite Gold Project
Stibnite, ID
3.16.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to the Proposed Action and Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to Access and Transportation. Additional descriptions of these regulations can be found in the SGP Access and Transportation Specialist Report (Forest Service 2022k).

Land and Resources Management Plan: National Forest Land and Resource Management Plans embody the provisions of the NFMA and guide natural resource management activities on NFS land. The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for access and transportation and include various objectives, guidelines, and standards for this purpose.

National Forest Management Act: The NFMA directs roads be designed to standards appropriate for intended uses and requires the revegetation of roads within 10 years of the termination of temporary and undeveloped roads created under contract, permit, or lease unless it is later determined that the road is needed for use as part of the National Transportation System (16 USC 1608 [b] and [c]).

Forest Roads and Trail Act Easements: Section 2 of the FRTA authorizes the road and trail systems for National Forests, the granting of easements across NFS lands, the construction of maximum economy roads, and the imposing of requirements on road users for maintaining and reconstructing roads (16 USC 532 et seq.). FSM 7703.3 states that, “Wherever possible, transfer jurisdiction over any NFS road and associated Forest transportation facilities (FSM 7705) to the appropriate public road authority when the road meets any of the following criteria: a) More than half the traffic on the road is not related to administration and use of NFS lands; b) The road is necessary for mail, school, or other essential local governmental purposes; c) The road serves yearlong residents within or adjacent to NFS lands” (Forest Service 2016d).

Travel Management Rule: Travel management planning is regulated by 36 CFR 212, 251, 261, and 295 – Travel Management; Designated Routes and Areas for Motor Vehicle Use; Final Rule. The final rule, effective in 2005, requires designation of roads, trails, and areas that are open to motor vehicle use by class of vehicle and applies to both summer and winter travel. The Travel Management Rule is divided into three subparts: A, B, and C (Forest Service 2019d).

Subpart A is the administration of the Forest Transportation System and includes the definitions for Part 212, which governs administration of the Forest Transportation System, designation of roads, trails, and areas for motor vehicle use (including OHVs). The PNF and BNF both completed a travel analysis process in September 2015 to inform future NEPA travel management decisions including identification of the minimum road system, identification of unneeded roads to be decommissioned or converted to other uses, and other changes to NFS roads, which include revisions to motor vehicle use designation (Forest Service 2019d, 2019e, 2019f).

Subpart B is the designation of roads, trails, and areas for motor vehicle use. The motor vehicle use map is developed under 36 CFR 212.51 (Forest Service 2019d). Subpart C designates and regulates use
specifically for OSVs. The Forest Service issued orders including maps showing the areas where OSV use is allowed, prohibited, or restricted.

State of Idaho Rules: The Idaho Surface Mining Act (Title 47, Chapter 15) requires the state to regulate mining activities, including but not limited to, mineral exploration, mine operations, reclamation of lands affected by exploration and mine operations. Implementing regulations under IDAPA 20.03.02 include provisions regarding the design, construction, maintenance, and reclamation of mining roads.

Valley County Master Transportation Plan: Valley County adopted its 2008 Master Transportation Plan to address the impacts of growth on the existing transportation system in the western portion of the county along SH 55 (Valley County 2008a). The Master Transportation Plan accounts for future growth and changes in land uses under Valley County’s jurisdiction. Valley County proposed recommendations for future improvements to the Valley County transportation network to support this anticipated growth.

Forest Service Manuals: FSM 2700 provides direction for special uses management on NFS lands. Chapter 2730 covers policies, authorities, and direction for granting rights-of-way for roads and trails across NFS lands and interests in lands. FSM 5400 covers landownership and Chapter 5460 provides direction concerning right-of-way acquisition. FSM 7700 provides direction for the planning, construction, reconstruction, operation, and maintenance of the Forest Transportation System.

3.16.4 Affected Environment

3.16.4.1 Existing Road Transportation Network

The Stibnite Mining District has been explored and mined since the early 1900s and included activities such as road construction and exploration. Many of the forest roads in the area were originally built to access mining claims or other remote sites and tend to be very steep, rocky, and winding (Forest Service 2019d).

The transportation network in the analysis area includes SH 55, Valley County roads, and NFS roads. Valley County maintains Warm Lake Road, Johnson Creek Road, and McCall-Stibnite Road on NFS lands through easements issued under the FRTA (Figure 3.16-1). For the purposes of this section, McCall-Stibnite Road is presented as three segments to provide a more location-specific discussion of existing conditions. These three segments include: Lick Creek Road (from SH 55 east to SFSR Road), East Fork Road (from SFSR Road east to the village of Yellow Pine), and Stibnite Road (from the village of Yellow Pine east to the Operations Area Boundary). There are approximately 130 miles of state roads, approximately 278 miles of Valley County roads, and approximately 1,557 miles of NFS roads in the analysis area.

Table 3.16-1 lists the existing primary roads in the analysis area by name, NFS road or CR number, a brief description of the route. The road width of SH 55 generally spans from 20 to 24 feet and the average posted speed limit is 55 miles per hour. Valley County road surface widths range from 14 to 26 feet and general speed limits range from 20 to 50 miles per hour (Valley County 2008b). NFS road surfaces in the SGP area range from 10 to 16 feet wide and most NFS roads do not have posted speed limits, but generally have a design speed limit of 5 to 15 miles per hour. Most roads in the PNF and BNF are single-lane, native surfaced roads with high rock fragment content from the rocky terrain and include pullouts.
for passing vehicles. General maintenance during snow-free months consists of grading and re-compacting the road surface, intermittent dust control, and periodic cleaning of drainage culverts and ditches.

The Forest Service Road Maintenance Levels (NFS MLs) are defined by the FSH 7709.59 – Road Systems Operations and Maintenance as the level of service provided by, and maintenance required for, a specific road which are consistent with road management objectives and maintenance criteria (Forest Service 2009c). Maintenance levels are summarized below:

- **Maintenance Level 5** – “Assigned to roads that provide a high degree of user comfort and convenience. These roads are normally double lane, paved facilities.” Some may have an aggregate surface and dust abatement may be used. They are usually an arterial or collector road. Typically, connect to state roads and CRs and include some developed recreation roads.

- **Maintenance Level 4** – “Assigned to roads that provide a moderate degree of user comfort and convenience at moderate traffic speeds. Most roads are double lane and have an aggregate surface.” However, some roads may be single lane. Some roads may be paved and/or dust abated. May connect to state and CRs and include some developed recreation roads.

- **Maintenance Level 3** – “Assigned to roads open and maintained for travel by a prudent driver in a standard passenger car. User comfort and convenience are not considered priorities.” Roads in this maintenance level are typically low speed, single lane with turnouts and spot surfacing. Some roads may be fully surfaced with either native or processed material. May include some dispersed recreation roads.

- **Maintenance Level 2** – “Assigned to roads open for use by high clearance vehicles. Warning signs and traffic control devises are not provided with the exception that some signing, such as W-18-1 ‘No Traffic Signs,’ may be posted at intersections. Motorists should have no expectations of being alerted to potential hazards while driving these roads. Long haul may occur at this level.” These are local roads that connect to collectors and other local roads and may not be passable during periods of inclement weather.

- **Maintenance Level 1** – Assigned to intermittent service roads during the time they are closed to vehicular traffic, typically more than 1 year. Basic custodial maintenance is performed to keep damage to adjacent resources to an acceptable level and to perpetuate the road to facilitate future management activities. Roads receiving maintenance level 1 may be of any type, class, or construction standard, and may be managed at any other maintenance level while they are open for traffic. While being maintained at level 1, they are closed to vehicular traffic, but may be open and suitable for non-motorized uses.

Source: Forest Service 2005b, 2018c, 2019d, 2019e, 2019f, -2019g; Valley County 2014, 2019c
*Warren-Profile Gap Road is outside of the analysis area but could be used to access the SGP when connecting from the north to Stibnite Road.

\(^1\)Roads Open to Highway Legal Vehicles = These roads are open only to motor vehicles licensed under state law for general operation on all public roads within the state.

\(^2\)Roads Open to All Vehicles = These roads are open to all motor vehicles, including smaller OHVs that may not be licensed for highway use (but not to oversize or overweight vehicles under state traffic law).

\(^3\)Unless otherwise noted, FR roads are closed by snow in the winter and re-open once snow melts in the spring.
The maintenance of certain NFS roads is coordinated between the Forest Service and Valley County through Schedule A agreements. Typically, NFS road maintenance activities (including dust control, removal of debris from roadway and rights-of-way, road repair, and snow removal) are coordinated with the Valley County Roads and Bridge Department. Most Valley County backcountry roads are closed through the winter and melt off in the spring (Valley County 2017). Similarly, NFS roads are closed by snow in the winter and re-open once the snow melts off in the spring. Therefore, roads do not open for through-traffic until at least mid-June and often close to public use as early as October 15.

### 3.16.4.2 Primary Routes

There are three existing primary routes within the analysis area to access the Operations Area Boundary from Cascade or McCall: Johnson Creek, Lick Creek, and SFSR routes as shown on Figure 3.16-1. All of the routes require the use of Idaho SH 55.

#### Johnson Creek Route

During non-winter conditions (roads clear of snow), the Operations Area Boundary can be accessed from the City of Cascade by traveling northeast on Warm Lake Road for about 34 miles to Landmark, then north on Johnson Creek Road for approximately 25 miles to the village of Yellow Pine, and approximately 14 miles east on the Stibnite Road portion of McCall-Stibnite Road (Stibnite Road). The Johnson Creek Route, which only includes Johnson Creek Road and the Stibnite Road portion of McCall-Stibnite Road, is currently used to access the Operations Area Boundary during the summer.

The Johnson Creek Road is a county maintained, native surface road that is open to vehicles with seasonal restrictions due to snow. During the winter, Valley County plows approximately 10 miles of Johnson Creek Road from Yellow Pine to Wapiti Meadow Ranch and Perpetua (under agreement with Valley County) plows along Stibnite Road. Valley County grooms the remaining 17 miles of Johnson Creek Road from Wapiti Meadow Ranch to Warm Lake Road at Landmark for OSV use. Valley County does not plow Warm Lake Road from Warm Lake to Landmark. This section is a designated groomed OSV route.

The Stibnite Road portion of the route is also a county-maintained native surface road, open to all vehicles with seasonal restrictions due to snow. This road is plowed in the winter by Perpetua through an agreement with Valley County. Stibnite Road connects to Thunder Mountain Road on the southeastern portion of the Stibnite site and currently provides public access through the site.

#### Lick Creek Route

The SGP also can be accessed from McCall during non-winter conditions by traveling east on the Lick Creek portion of McCall-Stibnite Road (Lick Creek Road) for approximately 37 miles to the East Fork South Fork portion of McCall-Stibnite Road (East Fork Road), then approximately 16 miles to the village of Yellow Pine, and approximately 14 miles east on Stibnite Road. Lick Creek Road is not maintained during the winter; however, East Fork Road and Stibnite Road are plowed from SFSR Road to Yellow Pine by Valley County and from Yellow Pine to the Operations Area Boundary by Perpetua to access their private land inholdings in the area.
**South Fork Salmon River Route**

Additionally, the Operations Area Boundary can be accessed year-round from Cascade by traveling approximately 24 miles northeast on Warm Lake Road to the intersection with SFSR Road, then north on SFSR Road for approximately 30 miles to McCall-Stibnite Road, and approximately 30 miles east on McCall-Stibnite Road (i.e., East Fork Road and Stibnite Road). Some segments along SFSR Road have sharp curves which can be challenging for heavy vehicle travel. However, this route currently provides the only access to the Operations Area Boundary during winter months.

**Warm Lake Road**

Warm Lake Road (CR 10-579) is a two-lane (one lane each direction), asphalt-paved roadway with lane markings open year-round to all vehicles from SH 55 to Warm Lake. The road starts in Cascade at an intersection with SH 55, which is a major north-south transportation corridor. This intersection would be used by all mine-related traffic through all phases of the SGP. The Warm Lake Road continues eastward for approximately 35 miles, ending at Johnson Creek Road (CR 10-413) at Landmark. Warm Lake Road is under the jurisdiction of Valley County. Currently, Valley County does not maintain Warm Lake Road in winter beyond Warm Lake Lodge. With adequate snowpack, an 8-mile segment of the Warm Lake Road route east of Warm Lake Lodge is used as an OSV route, allowing access into Landmark and points beyond.

### 3.16.4.3 Existing Stream Crossings

Existing stream crossings along the existing Johnson Creek, Stibnite, and Burnt Log roads are shown on Figure 3.16-1. There are 213 existing stream crossings along existing main access roads in the analysis area. These crossings include intermittent and perennial streams and irrigation canals and ditches (USGS 2021a). Additional details on existing stream crossings are found in the SGP Access and Transportation Specialist Report (Forest Service 2022k).

### 3.16.4.4 Existing Seasonal Access for OHVs and OSVs

OHVs can access the roads and trails throughout the analysis area during both summer and winter seasons. Currently, OHVs can access the Operations Area Boundary primarily from Stibnite Road to Thunder Mountain Road in order to reach Monumental Summit and the Lookout Mountain Trailhead in the summer. More detailed discussion on existing recreational access within the recreation analysis area is provided in Section 3.19.

During the winter, numerous roads in the analysis area are plowed for vehicle use or groomed for OSV use (Valley County 2019c). Specifically, Valley County plows the following roads/road sections for highway legal vehicle use during the winter: East Fork Road from SFSR Road to Yellow Pine; Johnson Creek Road from Yellow Pine to Wapiti Meadow Ranch, the beginning and end portions of Lick Creek Road, and Warm Lake Road from SH 55 to Warm Lake under existing FRTA easements. Valley County also plows SFSR Road for use during the winter under a Schedule A cooperative maintenance agreement. Perpetua plows Stibnite Road from Yellow Pine to the SGP under an annual road maintenance agreement with Valley County to maintain access to their private land inholdings in the area.
Valley County currently grooms for OSV use the portion of Johnson Creek Road from Wapiti Meadow Ranch to Warm Lake Road (approximately 17 miles) and the length of Warm Lake Road from Warm Lake to Landmark (approximately 11 miles). Valley County also grooms Burnt Log Road for OSV use (approximately 9.8 miles total: 6 miles groomed and 3.8 miles of infrequently groomed). Cabin Creek Road is currently used during the summer and is not a groomed OSV route.

### 3.16.4.5 Existing Traffic Conditions

Existing vehicle traffic was determined by traffic count data collected on local roadways and at SH 55 intersections in the analysis area (HDR 2017l, 2017m; ITD 2017). Traffic count data was collected to record two-way road usage at nine sites from July through October from 2015 through 2016.

**Table 3.16-2** summarizes the baseline traffic volumes (i.e., AADT) for key roadway segments in the analysis area.

</table>

[^1]: Data was collected in 2015 or 2016 except for Warm Lake Road data collected in 2017. 2019 data from the ITD was available for SH 55, Warm Lake Road, Johnson Creek Road, Stibnite Road, and Burnt Log Road. AADT is calculated by Total Recorded Count/Number of Days Recorded. All figures have been rounded up to whole numbers.

[^2]: Average daily traffic count data provided by Forest Service for calendar year 2014 at Lick Creek Summit (35 AADT), East Fork (Eiguren Ranch) (37.8 AADT), South Fork (confluence) (34.7 AADT), Profile Summit (14.1 AADT), and Stibnite (18.1 AADT) support the data provided in Table 3.16-2. However, for consistency purposes, the 2015, 2016, and 2019 data collected would be used to account for traffic counts along the segments.

[^3]: A portion of the traffic turns off onto Warren-Profile Gap Road towards Big Creek/Edwardsburg (approximately 5 to 18 vehicles between 2014 through 2016). However, for purposes of this analysis, all traffic on Stibnite Road between Yellow Pine and the SGP is considered.

[^4]: This road considers traffic counts available from 2015-2017 data as more recent traffic counts for the specific road segments from SFSR Road to Yellow Pine were not available from the ITD.

[^5]: The traffic counts are assumed to include OHVs only. These roads include 2015-2017 traffic counts as more recent data was not available from the ITD.

The traffic volumes along the key roadway segments decrease with distance from SH 55. SH 55 is a public highway classified by Valley County as a principal arterial per the ITD functional classification that provides for relatively high travel speeds and minimum interference to through movement (American Association of State Highway and Transportation Officials [AASHTO] 2018; Valley County 2008a). Warm Lake Road has the most daily traffic of the county and NFS roads in the analysis area. Many recreational facilities are located off this road including numerous facilities near Warm Lake. Residences
are spread out along Warm Lake Road within 4 miles of SH 55 and along McCall-Stibnite Road in Yellow Pine and north to Big Creek using Warren-Profile Gap Road. Warm Lake Road, Johnson Creek Road, and McCall-Stibnite Road are considered county collector roads per ITD functional classification (Valley County 2008a).

Traffic volume in the analysis area is mainly attributed to recreational activities and residential traffic. Other activities could include fuels management, road and utility maintenance activities, and timber harvest. In addition, current traffic levels in the analysis area also can be attributed to the activities that have been ongoing since 2009 for exploration purposes, monitoring, background studies, and private property infrastructure maintenance. Traffic volume and traffic behavior vary depending on the day of the week and the season. Valley County has many summer recreational areas that attract visitors from May through October with peak levels in June, July, and August. Although the AADT is less during the winter months, winter driving conditions influence the amount of traffic (Valley County 2008a).

3.16.4.6 Vehicle Accidents

Vehicle accident data for full-size vehicles, motorcycles, and OHVs from 2000 through 2021 was obtained from Valley County Sheriff’s Department records for the six roads associated with the three existing primary access routes to the Operations Area Boundary. Warm Lake Road experienced an average of seven accidents per year from 2000 through 2021, followed by SFSR Road with an average of two accidents per year, Lick Creek Road with two accidents per year, Johnson Creek Road with one accident per year, and Stibnite Road and East Fork Road with no accidents on average per year (Ulberg 2017, VCSD 2022).

According to the Valley County Sheriff’s traffic incident records from 2000 through 2021, the causes of most accidents on the existing roadways fall under the general categories of driver error, vehicle mechanical issues, and environmental factors (Ulberg 2017, VCSD 2022).

3.16.4.7 Golden Meadows Exploration

The previously authorized Golden Meadows mineral exploration activities began in 2009 and currently use the existing road transportation network. The exploration area is accessed via the Johnson Creek Route during the summer and the SFSR Route during the winter. Activities include the construction of short temporary trails, reopening of former roads, and use of existing non-system roads to access adjacent areas of private inholdings or drill sites. These temporary roads would be reclaimed once access to adjacent areas of private inholdings is no longer required or when drilling is completed, and drill sites reclaimed.

3.17 Heritage Resources

3.17.1 Introduction

This section describes the existing (baseline) conditions relevant to Heritage Resources that have the potential to be affected by the SGP.
3.17.1.1 Definitions

For purposes of this report, the term heritage resource will be utilized in place of cultural resource to describe archaeological sites, historic buildings and structures, trails, roads, infrastructure, and other places of traditional, cultural, or religious importance that represent the physical aspects of the activities of past or present cultures. Heritage resources can be human-made or natural features and are, for the most part, unique, finite, and nonrenewable.

Although the terminology has been amended for purposes of this report, the definition of heritage resource is that of a cultural resource which is defined in the FSM 2300 under Section 2360.5, and as follows:

*an object or definite location of human activity, occupation, or use identifiable through field survey, historical documentation, or oral evidence. Cultural resources include prehistoric, historic, archaeological, or architectural sites, structures, places, or objects and traditional cultural properties (Forest Service 2008a).*

Categories of heritage resources described in this report are synonymous with those resources identified in the above-detailed definition. However, the analysis of potential impacts to heritage resources as detailed in Section 4.17 is limited to historic properties, as defined by Section 106 of the NHPA and its implementing regulations at 36 CFR 800. Historic properties are defined as:

*...any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior. This term includes artifacts, records, and remains that are related to and located within such properties. The term includes properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization and that meet the NRHP criteria (36 CFR 800.16).*

Historic properties include not only archaeological and historic architectural resources, but also CLs, and TCPs. As defined by the NPS, TCPs are a distinct category of historic property eligible for listing in the NRHP due to their association with cultural practices or beliefs rooted in a living community’s history and importance in maintaining the cultural identity of that community (Parker and King 1998). A TCP must be a tangible property, that is, a district, site, building, structure, or object as defined in 36 CFR 64.4 (FSM 2360.5). Its significance must be documented and evaluated in accordance with the four NRHP criteria (Parker and King 1998).

A TCP may be a building, site, district, object, or landscape. The significance must go beyond the past 50 years yet retain ongoing significance. Although the same seven aspects of integrity are relevant, National Register Bulletin 38 (Parker and King 1998) notes that the concept of integrity is applied somewhat differently for TCPs than it is for archaeological sites:

*In the case of a traditional cultural property, there are two fundamental questions to ask about integrity: 1) does the property have an integral relationship to traditional cultural practices or beliefs; and 2) is the condition of the property such that the relevant relationships survive (Parker and King 1998).*
CLs are defined by the NPS as:

A geographic area, including both cultural and natural resources and the wildlife or domestic animals therein, associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values. There are four general types of cultural landscapes, not mutually exclusive: historic sites, historic designed landscapes, historic vernacular landscapes, and ethnographic landscapes (NPS 2020).

Regulations under the NHPA and NEPA provide that impacts to TCPs and CLs, if applicable, be considered in the agency’s Section 106 consultation for any proposed federal agency action. Because Native American tribes can be affected by the policies and actions of the Forest Service in managing the lands and resources under its jurisdiction, the Forest Service has a duty to consult with them on matters affecting their interests. Because of this government-to-government relationship, efforts were and continue to be made to involve local tribal governments and to solicit their input regarding potential effects to heritage resources. The structure of formal government-to-government consultation is between tribal governing bodies (Executive Committee, Tribal Councils, Tribal Chairperson, traditional Chiefs, or those identified formally by a tribe’s governing body as ‘representative’ of that tribe’s interests) and Forest Service Line Officers. Staff-to-staff meetings usually include Forest Service technical specialists and tribal liaison and technical specialists. Tribal consultation for the SGP was initiated with each tribe in the spring of 2017 and is ongoing.

3.17.1.2 NRHP Criteria and Integrity

The criteria for determining whether cultural resources are eligible for listing in the NRHP and therefore considered historic properties are provided in 36 CFR 60.4. The NRHP criteria are as follows:

The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association; and

a) That are associated with events that have made a significant contribution to the broad patterns of our history; or

b) That are associated with the lives of persons significant in our past; or

c) That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or

d) That have yielded, or are likely to yield, information important in prehistory or history.

While nearly all sites have the potential to yield information useful in addressing a limited number of research questions, this limited potential alone is not considered enough to qualify a site for inclusion in the NRHP under Criterion D. Federal guidelines encourage the use of a set of research questions that are generally recognized as important research goals as a means of evaluating significance. If a site contains information that is demonstrably useful in answering or refuting such questions, it can be considered a significant site under Criterion D.
In order to be a historic property, resources must meet one or more of the NRHP criteria and must retain the aspects of integrity of location, design, setting, materials, workmanship, feeling, and association. The NPS NRHP guidance defines integrity as:

...the ability of a property to convey its significance. To be listed on the NRHP, a property must not only be shown to be significant under the NRHP criteria, but it must also have integrity. The evaluation of integrity is sometimes a subjective judgment, but it must always be grounded in an understanding of a property’s physical features and how they relate to its significance.

Historic properties either retain integrity (that is, convey its significance) or they do not. Within the concept of integrity, the NRHP criteria recognize seven aspects or qualities that, in various combinations, define integrity. To retain historic integrity a property will always possess several, and usually most, of the aspects. The retention of specific aspects of integrity is paramount for a property to convey its significance. The seven aspects are: location, design, setting, materials, workmanship, feeling, and association (NPS 1995).

A property does not have to exhibit all seven aspects of integrity but must retain those aspects that are essential for conveying its significance. For example, integrity of association with an event or person is critical for sites that are significant under Criteria A or B, and integrity of design, material, and workmanship would be important to a building significant under Criterion C. Integrity of location, materials, and workmanship would be important for a precontact artifact scatter significant under Criterion D for its research value in understanding precontact technology and site function.

3.17.2 Heritage Resources Area of Analysis

The analysis area for heritage resources includes the area where effects may be caused by the proposed activities (FSH.1909.15.10, 15.2a). The analysis area is coterminous with the Section 106-defined APE as detailed below.

Per 36 CFR 800.16(d), an APE is defined as...the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist. The APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking…” The APE defines that area within which the identification of historic properties will occur.

The APE encompasses the geographic area within which the SGP may cause alterations in the character or use of historic properties, if any such properties exist. Two APEs were identified for the SGP (Figure 3.17-1; Table 3.17-1). The physical APE encompasses the area where physical disturbance may occur. It includes the mine site, access roads, utilities, and offsite facilities along with a 100-meter (m) (330 foot) buffer zones around most of these areas to account for variations in alignments, access, and other incidental ground disturbance. The VAV APE is generally defined as the same as the physical impacts APE surrounding the mine site but extending out to the next higher ridgeline in some areas, a 0.8-km (0.5 mile) buffer on either side of the existing access roads and existing transmission line, a 1.6-km (1 mile) buffer on either side of the Burntlog Route and segment of new transmission line, and a 0.8-km (0.5 mile) buffer surrounding off-site facilities; these areas encompass the extent of potential SGP-related visual, auditory, and vibratory impacts to historic properties. Noise and vibration attenuate as a function of

Areas of Potential Effects
Stibnite Gold Project
Stibnite, ID

Base Layer: ESRI World Shaded Relief Service
Other Data Sources: Perpetua; State of Idaho Geospatial Gateway (INSIDE Idaho); Boise National Forest; Payette National Forest

* Project Components are associated with all Action Alternatives
** Burntlog Maintenance Facility only pertains to 2021 MMP
*** Landmark Maintenance Facility only pertains to Johnson Creek Alternative.
distance from the source, ground absorption, atmospheric conditions, and the presence of physical barriers. Visual impacts from visible physical features on the landscape also decrease with distance. Given the location of the SGP in a mountainous area, natural topography would conceal the mine and associated facilities from certain lines of sight.

Table 3.17-1 Summary of the APEs

3.17.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternatives. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to heritage resources. Additional descriptions of these regulations can be found in the SGP Heritage Resources Specialist Report (Forest Service 2022l).

National Forest Land and Resource Management Plans: Heritage resources are managed consistently with established and approved Forest Service Heritage Program Plans; FSM 2300, Chapter 2360; and FSH guidance (FSH 2309.12).

Implementation of Heritage Program planning is completed to identify priority heritage assets, recommend allocation of heritage resources to management categories that reflect their primary value (i.e., cultural/traditional, scientific, interpretive, or continued use), develop historic preservation management plans, and guide implementation of compliance, protection, and stewardship activities.

The Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) regulate heritage resources to achieve the desired outcomes and conditions for the Heritage Program.
In addition to specific standards and guidelines, the Payette Forest Plan and Boise Forest Plan describe the desired conditions for Heritage Program resources in the following way:

*People visiting the National Forest should be able to explore, enjoy, and learn about cultural heritage. As visitors travel through landscapes and experience diverse environments and cultures, they make a personal connection with the land and the people and have an opportunity to reflect on the relevance of the past and the land to their daily lives. Sites determined to be significant, under the NHPA, are inventoried, protected, and if warranted, nominated to the NRHP (Forest Service 2003a, 2010a).*

**Antiquities Act of 1906:** The Antiquities Act of 1906 protects all historic and prehistoric sites on federal lands and prohibits excavation or destruction of such antiquities unless a permit (Antiquities Permit) is obtained from the Secretary of the department that has jurisdiction over those lands. In addition, it authorizes the President to declare areas of public lands as National Monuments and to reserve or accept private lands for that purpose. (54 U.S.C. §§320301-320303).

**National Historic Preservation Act:** The NHPA of 1966, as amended through December 16, 2016 (Public Law [P.L.] 89-665, as amended by P.L. 96-515; 54 USC 300101 *et seq.*) is the principal federal law protecting historic properties.

Section 106 of the NHPA (54 USC 306108) directs all federal agencies to consider the effect of their undertakings (i.e., actions, financial support, and authorizations) on any historic properties. The Advisory Council on Historic Preservation (ACHP) regulations at 36 CFR 800 implement Section 106. Procedures are outlined for identifying resources; evaluating their significance; assessing effects; implementing measures to mitigate adverse effects; and consulting with the ACHP, State Historic Preservation Offices (SHPOs), Tribal Historic Preservation Offices, and other interested parties. The NRHP is used as a planning tool under these regulations to help federal agencies evaluate the significance of cultural resources. Additionally, the NHPA requires federal agencies to consult with Native American tribes to determine whether there are properties of traditional religious and cultural importance to Indian tribes that may be eligible to the NRHP (54 USC 302706).

**National Environmental Policy Act:** NEPA, as amended (P.L. 91-190, January 1, 1970, as amended by P.L. 94-52, P.L. 94-83, and P.L. 97-258; 42 USC 4321-4347) implemented by Council on Environmental Quality regulations at 40 CFR 1500-1508 requires agencies to consider the effects of proposed actions before making decisions that affect historic properties and the human environment. Under the NEPA, agencies must consider potential “cultural” effects as well as effects on historic properties (40 CFR 1508.8).

For the SGP, the Forest Service has determined that a Programmatic Agreement (PA) is required to ensure compliance with 36 CFR 800. A PA addresses historic properties that may be affected by a project to minimize or resolve any potential adverse effects. A PA outlines measures for compliance with Section 106 of the NHPA, including but not limited to, protocols for the identification and evaluation of historic properties, permitting requirements, treatment of historic properties, monitoring requirements, inadvertent discovery protocols, curation, and treatment of human remains. The PA would identify known adverse effects to historic properties and provide a discussion of proposed mitigation measures that would be implemented. A PA is a legal document with signatories and concurring parties. Agency signatories,
invited signatories, and concurring or consulting parties would include the Forest Service, the USACE, the Idaho SHPO, the ACHP, IPCo, Native American tribes, as well as Perpetua. The PA would be in place prior to completion of the ROD.

Archaeological Resource Protection Act (ARPA) of 1979: The purpose of ARPA, is to secure the protection of archaeological resources and sites which are on public lands and tribal reservation lands, and to foster increased cooperation and exchange of information between governmental authorities, the professional archaeological community, and private individuals having collections of archaeological resources. The law applies to any agency that receives information that a direct or federally assisted activity could cause irreparable harm to prehistoric, historic, or archaeological data and provides criminal penalties for prohibited activities (16 U.S.C. § 470aa).

Native American Graves Protection and Repatriation Act (NAGPRA): The NAGPRA became law in 1990; the regulations implementing the statute were completed and went into effect in January 1996. This law formally affirms the rights of Native American tribes, Native Alaskan entities, and Native Hawaiian organizations to custody of Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony with which they have a relationship of cultural affiliation. NAGPRA gives even stronger custody rights to lineal descendants when such a close relationship can be documented. In addition, the law and regulations describe procedures designed to ensure that all Americans can derive educational, historical, and scientific value from the remains and objects covered by the statute through public interpretation, documentation, and study (25 U.S.C. § 3001 et seq.).

Executive Order 11593 – Protection and Enhancement of the Cultural Environment: This EO (EO), signed in 1971, furthers the NEPA of 1969, the NHPA of 1966, and the Antiquities Act of 1906 by requiring federal agencies to administer cultural properties under their control and direct their policies so that federally owned sites, structures, and objects of historical, architectural, or archeological significance are preserved, restored, and maintained. To achieve this goal, federal agencies must review properties under their jurisdiction and nominate properties that qualify for listing on the NRHP. If any Federal action planned will substantially alter or demolish a property listed on the NRHP, federal agencies must make detailed records of the property and deposit those records in the Library of Congress for future use. Federal agencies must annually prepare and submit to the Secretary of the Interior and the ACHP procedures to provide for the maintenance, preservation, and restoration of federally owned sites. The EO also enumerates responsibilities of the Secretary of the Interior regarding such properties.

State and Local Policy: The Idaho State Historic Preservation Plan, Preserving the Past, Enriching the Future, Idaho State Historic Preservation Plan, 2016-2022, (ISHPO 2016) discusses trends affecting Idaho’s cultural resources, presents preservation goals and objectives, and introduces broadly drawn categories for historic contexts as a framework for further development of this tool. The plan seeks to establish priorities and goals for historic preservation in Idaho and serve to unite a variety of historic preservation groups and professionals in implementing the plan’s goals through an established framework.

The following state laws, as summarized in the Idaho State Historic Preservation Plan, apply to heritage resources:
• **Idaho Code 18-7027**: Prohibits the disturbance of prehistoric human burials, or the possession of human remains or artifacts removed from a burial, unless the excavation is conducted by a qualified archaeologist with the prior approval of the State Historical Society and the appropriate Indian tribe.

• **Idaho Code 27-501**: Assigns responsibilities to the agency for consultation, determination of appropriate actions, and providing for re-interment of human remains that have been disturbed.

• **Idaho Code 33-39**: Provides for the creation of an Idaho Archaeological Survey and designates the State Archaeologist as director.

• **Idaho Code 67-41**: States that the agency [Idaho State Historical Society] shall: Identify, preserve, and protect sites, monuments, and points of interest in Idaho of historic merit. (67-4114); Protect archaeological and vertebrate paleontological sites and resources on public land. (67-4119); Govern the agency and administer the powers and duties required to preserve and protect any historical record of the history and culture of Idaho” (67-4123). Senate Bill 1011 (2009), passed by the Senate and House and signed into law by the governor April 14, 2009, defines “historical record” as “any record, artifact, object, historical or archaeological site or structure, document, evidence or public or private writing pursuant to the provisions of title 9, Idaho Code, relevant to the history of the state of Idaho.”; Encourage and promote interest in the history of Idaho. (67-4126 [2]); Collect, preserve, and exhibit artifacts and information illustrative of Idaho history, culture and society. (67-4126 [3]); and Identify historic, architectural, archaeological, and cultural sites, buildings, or districts, and to coordinate activities of local historic preservation commissions. (67-4126 [14]).

• **Idaho Code 67-46**: Gives authority to the agency to carry out the preservation and protection of the state’s historic, archaeological, architectural, and cultural heritage resources. This section of code also authorizes municipalities to create historic preservation commissions, establish design review for historic districts, and carry out other historic preservation efforts at the local level.

• **Idaho Code 67-65**: The Idaho Local Planning Act of 1975 requires a local governments’ comprehensive plan must include a component for “Special Areas or Sites.” There must be an analysis of areas, sites, or structures of historical, archaeological, or architectural significance within the jurisdiction of the governing board.

### 3.17.4 Affected Environment

The heritage resources analysis area is in the upper East Fork SFSR drainage, approximately 3 miles west of the FCRNRW and approximately 10 air miles southeast of the village of Yellow Pine. The heritage resources analysis area comprises a heavily vegetated landscape marked by major river canyons and tributaries. The mine site is situated in the Salmon River Mountains, a high-relief mountainous physiographic province in central Idaho, and rests at an elevation of approximately 6,500 feet, with nearby mountains rising to elevations of approximately 7,800 to 8,900 feet amsl (Mitchell 2000). Major waterways include the East Fork SFSR, Meadow Creek, and Sugar Creek, and their numerous tributaries (Mitchell 2000). Vegetation in the heritage resources analysis area varies from riparian marsh wetland areas to spruce-fir forests.

Portions of the heritage resources analysis area have historically been heavily mined and modern mining disturbance occurs to the present day. The analysis area has been subject to extensive mining-related
activities over the past century including underground and open pit mining, heap leaching, ore processing, smelting, tailings disposal, development rock disposal, construction of town and camp sites, haul roads, powerlines, landfills, waterway diversions, hydro-power dam development (and failure), etc. These past mining activities have resulted in impacts to the natural environment including deforestation and accelerated erosion; increased sedimentation; elevated metals loading in surface and ground waters; diversion and degradation of natural waterways, including the East Fork SFSR; blockages to anadromous fish passage; impaired water quality; and compromised fish habitat, waterways, and wetlands. Additionally, extensive forest fires have compounded the human-created impacts and have increased soil erosion and impacted water quality. Other impact agents include but are not limited to previous road construction, and recreation related impacts such as dispersed camping, and non-motorized and motorized trail development.

3.17.4.1 Cultural Context

Cultural context refers to the past human groups that have used the analysis area for various purposes throughout the precontact period and the contact or historic period. In addition, the cultural context provides some information concerning indigenous communities’ continued connections and practices in the analysis area along with the mining activities that have occurred at Stibnite during the modern era. More recent use of the analysis area has been related to mining (beginning in the mid-1800s), recreational activities, and traditional tribal hunting, fishing, and plant gathering among other practices. A historic context of the Stibnite area was prepared for the SGP (Midas Gold 2016a). Additionally, the Nez Perce Tribe, the Shoshone-Paiute Tribes, and the Shoshone-Bannock Tribes have prepared ethnographies of the analysis area (Battaglia 2018; Walker 2019; Lahren 2020). General archaeological themes in the analysis area and vicinity include pre-contact archaeology, ranching, settlement, Forest Service history, traditional practices, and mining. Detailed contextual information is presented in the Heritage Resources Specialist Report (Forest Service 2022l) and detailed ethnographic information is also included in the SGP Tribal Rights and Interests Specialist Report (Forest Service 2022q).

Pre-contact Period

Native Americans were present in central Idaho as early as 15,000 years before the present (B.P.) (Gannon 2019). Paleoindian tools have been recovered from archaeological sites in Valley County, including a Clovis projectile point, or spearhead, in Yellow Pine during excavations for a church in 1985. Artifacts also have been found along Johnson Creek and the Middle and South Forks of the Salmon River (Woods 2002). Eligible archaeological historic properties have been recorded along the area’s river corridors and in high elevations. More recent evidence of Archaic occupation in the analysis area is seen in precontact site 10VY1488, recorded in 2016. The site contains stone tool chipping debris and projectile point types that date to the Archaic period or from around 4,000 B.P. (Lahren and Pollock 2016).

Since the early systematic archaeological research work in Idaho of Swanson (Swanson 1972) and Butler in the 1960s and early 1970s (Butler 1978, 1986), a variety of precontact chronologies for Idaho have been developed by Pavesic (1978), Franzen (1981), Reed et al. (1986), Holmer (1986, 1994), Plew (2008), Meatte (1990), Lohse (1993), Roll and Hackenberger (1998), Yohe and Woods (2002), and Simms (2008). These researchers (among others) studied settlement, subsistence, technology, and cultural interaction of indigenous groups in the analysis area. These overviews provide understanding of the
different degrees of cultural continuity and variability presented in the archaeological record. Plew (2008) developed a chronology that combines some of these sequences.

**Paleoindian Tradition (15,000-9,000 B.P.).** The Paleoindian Tradition centers on the hunting of big-game animals that became extinct during the terminal phase of the Late Pleistocene or in the early Holocene. Paleoindian people were extensively mobile and engaged in a food economy driven by the availability of big game that ranged widely across the landscape (Simms 2008). It is assumed their diet also included small game and plants (Lohse 1993). Generally, archaeological evidence for the Paleoindian Tradition in upland areas of central Idaho are most clearly associated with the presence of Clovis and Western Stemmed Tradition projectile points (Beck and Jones 2010). Recent investigations at the Cooper’s Ferry Site on the Salmon River in western Idaho, however, suggest the possibility that Paleoindian peoples were present in the region approximately 16,000 years B.P., well before the traditionally accepted timeframe associated with Clovis technology (Davis et al. 2019). The Cooper’s Ferry site is also known by the Nez Perce Tribe as an ancient village site named *Nipéhe*.

**Archaic Tradition (8,000-250 B.P.).** At the end of the Paleoindian Tradition nearly 8,000 years ago, environmental conditions in Idaho became warmer and drier, resulting in lifeway changes and, thus, changes in artifact assemblages (Butler 1978). An important addition to the assemblage was the introduction of the atlatl and associated corner- and side-notched projectile points. In addition, material items associated with an increasingly diverse and complex hunter-gatherer society emerged (Plew 2008). Reed et al. (1986) divided the Archaic Tradition into three subperiods: Early, Middle, and Late, each lasting nearly 3,000 years. Lower Johnson Creek contains several sites representative of the Early Archaic period in western Idaho (Forest Service 2010a).

**Ethnohistoric Period**

Ancestors of the Nez Perce Tribe, Shoshone-Bannock Tribes, and Shoshone-Paiute Tribes were the aboriginal inhabitants of this region of Idaho. Their aboriginal territory covered parts of present-day Oregon, Washington, and Idaho. This area included several major river basins: the Columbia, the Salmon, the Snake, and the Clearwater (Indian Claims Commission 1961). The Nez Perce Tribe’s aboriginal territory and lifeways are associated with the Columbia Plateau, whereas the Shoshone-Bannock Tribes and Shoshone Paiute Tribes aboriginal territories and lifeways are associated with the Great Basin.

Prior to Euroamerican contact, the *Niimi’ipuu* (Nez Perce) were the dominant people of the Columbia Plateau, with a an estimated 17,000,000-acre territory in regions of Washington, Oregon, Montana, and Idaho, between the Cascade Range in the west to the Bitterroot Mountains in the east (Josephy 1971). Within the territory, several tribes from the Rockies in the east and the Pacific coast in the west were tied together via an extensive trade network. The *Niimi’ipuu* are part of the Sahaptin language family; they formed composite bands generally based on familial ties, language, and territory (Idaho Centennial Commission Native Americans Committee [ICCNAC] 1992; Walker 1982). The settlement and subsistence patterns of the *Niimi’ipuu* were varied and linked to resource distribution and environmental features (Churchill 1983). Anadromous fish, such as Chinook salmon, roots, such as camas, and a variety of game were, and continue to be, important subsistence resources (Hunn et al. 1998; Nez Perce Tribe 2019, 2020). The *Niimi’ipuu* engaged in fishing, hunting, and gathering across their vast aboriginal
territory, and these activities still play a major role in the culture, religion, subsistence, and commerce of the Nez Perce Tribe (Nez Perce 2017).

The Northern or Snake River Shoshone and Bannock, all part of the Numic language family, occupied an area generally along the Snake River Plain, but their territory also included most of southern Idaho, western Wyoming, and Montana, and south into Nevada and Utah (ICCNAC 1992; Murphy and Murphy 1986; Walker 1982). The Northern Paiutes left the Nevada and Utah regions for southern Idaho in the 1600s and traveled with the Shoshones in pursuit of bison; this band of Paiute became known as Bannocks (Shoshone-Bannock 2021). The northern portion of their territory in Idaho included present day Adams and Valley counties. The four Northern Shoshone band divisions included: (1) the Western Shoshone (Waareekas), including the Boise and the Bruneaus; (2) the Mountain Lemhi Shoshone, including the Dukudeka (Sheepeaters) and the Agaidikas (Salmoneaters); (3) the Northwestern Shoshone, including the Bear Lakes, Cache Valley, Bannock Creek, and Weber Ute; and (4) the Pohogue (Fort Hall) Shoshone (Forest Service and Bureau of Land Management 1997). The Newe (Shoshone-Bannock) traveled seasonally within their aboriginal territory, often visiting locations annually to gather and hunt (including fishing), among other practices throughout central Idaho’s Salmon River Mountains and other areas (Forest Service 2003a; Murphy and Murphy 1986). In the northern part of the territory were the Mountain Lemhi Shoshone, who wintered along the Lemhi River, a tributary of the SFSR. The Lemhi depended heavily on salmon runs in the Salmon River system for their subsistence. Fish were harvested either individually by harpoon or utilizing weirs across stream channels, basket traps, or seines and hand nets (Murphy and Murphy 1986). Important animals and plants for subsistence included salmon, deer, elk, moose, mountain sheep, bison, various nuts, seeds, berries, and roots, such as camas for food and osha/bear root for medicine. Small game animals, including, groundhog, jack rabbit, porcupines, and prairie dogs, also were used extensively especially in sagebrush steppe ecosystems (ICCNAC 1992; Walker 1982, 2019).

Ancestral bands of Western Shoshone and Northern Paiute traveled in small groups over a vast territory centered around southern Idaho, northern Nevada, and southeastern Oregon (Fowler and Liljeblad 1986; Thomas et al. 1986). The Dukudeka or Sheepeater band of Mountain Shoshone, a subset of Western Shoshone peoples, lived in parts of what is now the PNF Krassel District, McCall District, and the FCRNRW and the surrounding area and to the east into Montana and Wyoming. The Northern Paiute lived in two major bands in territories centering on the upper Snake and Owyhee Rivers, respectively. They used many of the same fishing and camas gathering areas as the Western Shoshone bands. Both the Western Shoshone and the Paiute were somewhat isolated by the Rocky Mountains and the Great Basin. They necessarily relied more on plant foods, such as sunflowers, wada seeds, currants, and huckleberries, plus small animals and insects. Much time was spent pursuing food based on seasonal cycles. In May, they left winter villages to gather roots and prepare salmon traps. At the end of the salmon runs, people dispersed to hunt and gather plants and insects. Communal rabbit and antelope drives and wada seed gathering occurred in early fall. By November, food had been stored, and the people returned to the winter villages (Walker 1982, 2019). More detailed tribal histories are provided in Section 3.24.

**Contact, Historic Period, and Modern Era**

The contact period is generally defined as beginning with the first Euroamerican and Native American contact. For this area, the Lewis and Clark Expedition of 1805 is most often referenced. Lewis and
Clark’s Corps of Discovery precipitated an era of rapid Euroamerican exploration and settlement, which advanced regionally with the arrival of early explorers, fur traders, and missionaries. Circa 1810, British and American fur trading posts were being established throughout the Pacific Northwest. However, contact was still limited in the remote mountains of central Idaho, but there were several meeting places known to the Euroamerican settlers and frontiersmen in Valley County, including an annual summer meeting at the north shore of Payette Lake where various indigenous peoples, including the Newe/Shoshone and the Niimi’ipuu/Nez Perce gathered.

By 1900, most members of the Nez Perce Tribe, the Shoshone-Bannock Tribes, and the Shoshone-Paiute Tribes lived on reservations away from the mountains of central Idaho (Forest Service 2003a). However, the analysis area is still used by and of interest to these tribes (Battaglia 2018; Forest Service 2003a, 2010a; Lahren 2021; Walker 2019). More detailed tribal histories are provided in the SGP Tribal Rights and Interests Specialist Report (Forest Service 2022q).

The communities of Yellow Pine and Roosevelt, as well as ranches along Johnson Creek, were first established in the early 1890s to support the mining boom in the nearby Big Creek area and the Thunder Mountain gold rush of the mid-1890s (Forest Service 2015c). Initial reports from the gold deposit at Thunder Mountain (the Dewey Mine) were very favorable, and, in 1902, its promise lured over 2,000 prospectors between 1902 and 1906, creating the boom town of Roosevelt. Thunder Mountain Road was established along a Native American travel corridor at this time to access Roosevelt from Emmett via Long Valley (Woods 2002). The mining boom at Thunder Mountain was short lived, as initial reports of the gold deposits were highly exaggerated. Mining ceased altogether in 1909 when a mudslide caused flooding and the subsequent evacuation and destruction of the community of Roosevelt. Thunder Mountain had a brief resurgence for a few years with an open pit at the Dewey Mine after gold prices had increased and access had been improved in the 1930s (McKay 2011).

The first work in the Stibnite-Yellow Pine Mining District, not to be confused with the smaller Stibnite Historic District, may have occurred as early as the 1860s, but the Stibnite area was not developed until after the turn of the 20th Century (Forest Service 2015c). Though ore deposits were discovered in the Stibnite area during the early 1900s in conjunction with the Thunder Mountain gold rush, Stibnite was more remote than other areas in the Stibnite-Yellow Pine Mining District, and, with the technology of the times, the gold and silver were difficult to separate from the antimony-gold-silver ore that was prevalent in the area.

There were two primary periods of heavy production in the Stibnite area: 1) a period encompassing World War I and World War II, which ended in the 1950s and 2) a period that began with exploratory activities in 1974 with intentions to re-open the historic mines, which led to open pit mining and seasonal on-off heap leaching through the 1990s (Midas Gold 2016a).

The community of Stibnite was established in the 1920s and substantially boomed during World War II when it swelled to a peak population of 1,500 permanent residents (Bertram 1986). The post office was established in Stibnite in 1927 and the community’s name was chosen because the town names of Meadow Creek and Bradley were already taken when Bailey applied for a post office (Bailey 1979; Woods 2002). Stibnite is an antimony sulfide, and the largest known deposits of that sulfide in the U.S. are found in the Stibnite-Yellow Pine Mining District (McKay 2011).
During World War II, the Stibnite mines were one of the nation’s leading producers of minerals needed in the war effort, including antimony and tungsten. The mines produced an estimated 90 percent of the nation’s domestic supply of antimony and 40 percent of its tungsten supply during this boom (Bertram 1986). By the end of the war, tungsten deposits were played out, and the mine continued with low-grade antimony and gold, but it was no longer profitable (Forest Service 2015c). By June 1952, production had ended, and, in 1957, mine operations ceased altogether. Beginning in 1954, homes and community buildings were abandoned or moved to Cascade, Yellow Pine, or McCall (Bertram 1986; Hart 1979; Mitchell 2000; Petersen 1999; Woods 2002).

In the 1970s, Ranchers Exploration and Development Company leased part of the mine at Stibnite, and plans were made to reopen it, but nothing happened until a decade later when Ranchers Exploration and Development Company merged with Hecla Mining Company and continued development work for a few more years. At the time, Hecla Mining Company negotiated a deal with Pioneer Metals to use their leach plant at Stibnite, and, by 1988, Yellow Pine Mine at Stibnite was producing the third-largest amount of gold in the state from open pit oxide ores mined in the Homestake area (northeast of the Yellow Pine pit) and at West End (Mitchell 2000). Waste rock from these operations was dumped close to these pits.

Throughout the 1980s and 1990s, several companies operated heap leach gold and silver facilities in the area around Meadow Creek near the former Stibnite mill and smelter location. Some of these leach pads have since been covered with fill, while the Hecla leach pad remains stacked with leached ore. Work under several different mining companies continued intermittently until 1997. This work left a deposit over 50 feet deep of spent heap leach ore in an area now known as the SODA, on top of the Bradley tailings. Exploration and evaluation work did not occur again until 2009 when affiliates of Perpetua began exploration work in the Hangar Flats area (Midas Gold 2016a).

**3.17.4.2 Heritage Resources Inventories**

In an effort to identify previously recorded heritage resources and previously conducted heritage resources surveys within the APEs, records searches were conducted by both the respective PNF and BNF Heritage Program staff and by Lahren (2020) on behalf of Midas Gold. A summary of the records searches and those results follow.

In April of 2012, a records search (#12221) from the Idaho SHPO to determine the presence or absence of previously recorded archaeological sites and the extent of survey coverage in and within 1 mile of the 2012 survey area, which focused on the mine area. The results of the 2012 SHPO records search were used, along with the results of the updated PNF and BNF records searches, to determine the number of investigations that have occurred in the analysis area. In total, this record search indicated that 53 archaeological investigations have been completed within the analysis area.

In November of 2021 and January of 2022, PNF staff requested a records search (#21462 and #22109, respectively) from the Idaho SHPO to update and augment the previous records searches performed for the SGP area. These included not only the SGP area but also other project components such as access roads and the associated transmission line corridor. The records searches included data from the Idaho Archaeological Inventory, the Idaho Historic Sites Inventory, and survey reports filed with the Idaho SHPO office. These records searches combined were conducted on the entire VAV APE to provide
adequate background information regarding heritage resources. A summary of the previous surveys is included in Appendix A of the SGP Heritage Resources Specialist Report (Forest Service 2022).

Recent surveys conducted within the APEs and associated with the SGP took place in 2018 and 2019, when AECOM conducted a re-evaluation of the Stibnite Historic District (Historic District); a survey of the 38.2-mile proposed Burntlog Route, and the 5.3-mile Riordan Creek reroute alignment. The final report of that fieldwork (AECOM 2020h) was submitted to the Idaho SHPO by the Forest Service. The Idaho SHPO responded with a concurrence letter on June 30, 2020 (Johansson 2020).

More recently, an archaeological survey was conducted under the CERCLA on the PNF in response to the 2021 ASAOC (EPA 2021d) for the mine site. The archaeological survey addressed activities including tailings removal, potential borrow areas, and water diversions in areas that had not been previously inventoried. As a result, 124.6 acres were inventoried (Hauer 2021). Eight archaeological sites were investigated (three new sites and five previously recorded sites) and the PNF has recommended that none of these sites are eligible for listing on the NRHP. The final report of findings was submitted to the PNF in December 2021. The report was submitted to the Idaho SHPO for review and concurrence in January 2022 and a response is pending.

The APEs encompass the Operations Area Boundary, which is defined as the area within which Perpetua would control public access. The Operations Area Boundary includes 14,221 acres of which over 12,000 acres has been inventoried for heritage resources, either through intensive pedestrian transects or reconnaissance survey if conditions were too steep or dangerous, previously disturbed conditions existed; therefore, over 80 percent of the Operations Area Boundary has been inventoried.

### 3.17.4.3 Heritage Resources

As identified through the records searches and as a result of the previous surveys documented with the SHPO through January 2022, a total of 240 heritage resources, including archaeological sites and above-ground resources, have been recorded in the APEs. Of the 240 heritage resources, 97 have been determined not eligible for listing on the NRHP and would require no further management. The remaining 143 sites, however, would require additional consideration and/or management if impacted by the SGP and its components and include 61 resources documented as eligible for listing on the NRHP, three National Register-listed resources, and 79 resources identified as unevaluated for listing on the NRHP. Further details on these sites can be found in the SGP Heritage Resources Specialist Report (Forest Service 2022).

Not all resources within the analysis area will be considered historic properties and may not be impacted by SGP activities dependent upon their eligibility and location. However, for purposes of the effects assessments, unevaluated resources will be treated as eligible until they are assessed in the field and eligibility determinations consulted with the Idaho SHPO and Native American tribal partners. Through consultation between the PNF and the Idaho SHPO office in 2020, the Stibnite/Meadow Creek Historic District (10VY262/85-335; NR Inventory #87001186) was re-evaluated for its NRHP eligibility and was determined to no longer be eligible for listing on the NRHP. The SHPO concurred with the PNF’s determination of no longer eligible for listing on the NRHP by letter dated January 27, 2021. No further
management consideration for the Stibnite Historic District or individual associated resources located within the historic district, as defined in the correspondence between the PNF and the SHPO, is required.

### 3.17.4.4 Traditional Cultural Properties and Cultural Landscapes

Ethnographic studies have been completed for the SGP by the Nez Perce Tribe (Battaglia 2018), the Shoshone-Paiute Tribes (Walker 2019), and the Shoshone-Bannock Tribes (Lahren 2020) to assist in identifying TCPs and CLs, as defined by the NPS. The Forest Service is in ongoing consultation with Tribes on how to appropriately publicly disclose information presented in the tribal ethnographic studies that identified potential TCPs or CLs within the analysis area for heritage resources.

The Nez Perce Tribe’s ethnography, reviewed by the Heritage Resources Program Manager, describes areas and resources that the Nez Perce Tribe is most concerned with and indicates the potential for TCPs and/or CLs to exist in the analysis area. However, specific TCPs or CLs, as defined by the NPS (NPS 2020; Parker and King 1998), are not currently disclosed to the public as they are considered confidential. General types of landscape features noted in the Nez Perce Tribe ethnography (Battaglia 2018) as having specific significance include: viewsheds and soundscapes, water and waterways, minerals, driftwood, culturally modified trees, hot springs, trails, and travel corridors. Further details regarding TCPs, CLs, and summaries of appropriate ethnographic data are presented in the Heritage Resources Specialist Report (Forest Service 2022).

The Shoshone-Paiute Tribes’ ethnography (Walker 2019) is framed as a broad overview of their cultural connection to the analysis area and does not go into specific locations of TCPs or CLs. However, general types of landscape features noted in the Shoshone-Paiute Tribes’ ethnography as having specific significance include: buttes; rock features and rock alignments; springs and hot springs; trails and travel routes; river and stream canyons; rock structures; valleys; and caves and rock shelters. The Shoshone-Paiute Tribes’ ethnography also identifies significant species of flora and fauna that may be located within the SGP APEs that are further detailed in the SGP Heritage Resources Specialist Report (Forest Service 2022).

The Shoshone-Bannock Tribes ethnography (Lahren 2020) identifies the SFSR and broader area as a cultural landscape that supports the hunting of salmon, gathering food, collecting berries, harvesting medicinal plants, and hunting big and small game, among other cultural practices. Details on other places of importance identified in the ethnography are presented in the SGP Heritage Resources Specialist Report (Forest Service 2022).

Currently, there are no TCPs or CLs as defined by the NPS and meeting NRHP eligibility criteria within the analysis area for heritage resources. However, the Forest Service will assess whether the tribal resources identified by the Tribes in the ethnographies meet the NPS definition of TCPs. The PA would include steps for identifying and documenting TCPs and CLs and a management plan for any such resources identified.
3.18 Public Health and Safety

3.18.1 Introduction

3.18.2 Public Health and Safety Area of Analysis

Public health and safety is related to the overall health and well-being of populations within the affects area of the SGP. The National Research Council guidance lists five general categories that should be addressed as part of a public health evaluation to systematically select the issues that need to be addressed for a project. These five categories are: environment, economy, infrastructure, services, and demographics. Five types of health impacts are assessed for each area (National Research Council 2011):

- **Chronic Disease**: For the purposes of this evaluation, chronic diseases are health conditions that persist for long periods of time (i.e., 3 months or longer) and are non-communicable, such as heart disease, cancer, or asthma.
- **Infectious Disease**: Infectious diseases are associated with viral, bacterial, or microbial infections and are commonly transferred from person to person through direct contact, such as influenza.
- **Injury**: Unintentional or accidental event resulting in injury or trauma, such as a car accident or fall.
- **Nutrition**: Impacts to health (positive or negative) associated with diet.
- **Well-being/psychosocial effects**: Well-being and psychosocial effects consider the social and cultural well-being of the populations.

Impacts to the environment are typically evaluated based on potential impacts to various environmental media (i.e., air, soil, groundwater, and surface water). This analysis focuses on whether hazardous pollutants could be emitted by activities of the SGP and enter environmental media at levels that could be a health concern. Health concern is evaluated by considering the amount of human exposure to potentially impacted environmental media. Human exposure to environmental media can occur through several pathways of exposure (e.g., inhalation of vapors or particulates in air, incidental ingestion or skin contact with impacted soils, and ingestion or skin contact with impacted groundwater or surface water).

In addition to hazards from pollutant-impacted environmental media, the existing terrain and characteristics of the environment can present certain natural hazards to public health and safety, such as:

- Geologic hazards (steep terrain, rock cliffs, avalanches, and landslides),
- Flash floods and water hazards, and
- Wildfires.

Economic conditions may have indirect impacts on health, as a result of the financial resources available to the local population or local government for health-related services.

Availability and changes to public services and infrastructure can have direct or indirect health benefits or consequences. For example, health benefits can occur if new water or sanitation systems reduce disease incidence rates for the local community. There may be negative impacts if new roads or transit corridors increase traffic accidents or negatively impact access to health-related services or activities.
Local demographics and the local population’s health status are relevant to this analysis, as some populations are more sensitive to project effects due to preexisting health conditions, access to health care, availability of health insurance (Gresenz and Escarce 2011; Hadley 2003; Hadley and Cunningham 2005; Newton et al. 2008), and the potential for increased stress or annoyance levels for populations living or recreating nearest to the mining areas due to noise or vehicle traffic.

### 3.18.3 Relevant Laws, Regulations, Policies, and Plans

While NEPA does not directly address effects on public health and safety, it does require that an integrated analysis of health effects be addressed for an environmental impacts analysis. The scope of this analysis is limited to affected communities outside of the Operations Area Boundary and associated facilities and does not include a direct evaluation of the anticipated workforce safety and health issues. All worker health issues are covered under the OSHA and the MSHA, as described below.

**Occupational Safety and Health Act of 1970** – This was passed to prevent workers from being killed or seriously harmed at work. This law created OSHA, which sets and enforces protective workplace safety and health standards. Under OSHA, employers have the responsibility to provide a safe workplace (OSHA 2019).

**The National Forest Land and Resource Management Plans** - These embody the provisions of the NFMA and guide natural resource management activities on NFS land. Physical, social, and biological resources on NFS lands are managed to achieve a desired condition that supports a broad range of biodiversity and social and economic opportunity. Payette Forest Plan (Forest Service 2003a), and the Boise Forest Plan (Forest Service 2010a) provide management prescriptions designed to realize goals for achieving desired condition for public health and safety and include various objectives, guidelines, and standards for this purpose.

**Valley County Comprehensive Plan** - “The purpose of the Comprehensive Plan is not to control land, but to prevent uses of land harmful to the community in general.” The underlying objectives of the plan promote the health, safety, and general welfare of the people of Valley County, and aim to protect citizens from unsafe or unhealthy conditions caused by growth and development in the county (Valley County 2018a).

### 3.18.4 Affected Environment

Many natural and human-made public health and safety hazards are present in the analysis area, ranging from avalanches and wildfires to past and present storage and transportation of hazardous materials related to mine operations. Most of the analysis area is open to the public as most of the land is public land managed by the Forest Service.
Common users of the analysis area include Perpetua and Forest Service employees, residents of the village of Yellow Pine, tribal members, and recreationists. Recreation is a major use throughout much of the analysis area, and activities commonly include hunting, fishing, paddle boating, sightseeing, hiking, camping, all-terrain vehicle use, snowmobiling, and horseback riding. The remote nature of the analysis area presents numerous challenges for emergency operations, which include emergency management services and evacuation procedures.

The following section includes an assessment of the existing environmental conditions, socioeconomic conditions, public services and infrastructure related to public health and safety, and demographics with respect to land use and baseline community health conditions.

### 3.18.4.1 Environment and Health

Public health impacts associated with the environment could include exposure to pollutant-impacted media (e.g., air, soil, groundwater, and surface water), as well as potential physical hazards associated with the rugged, mountainous terrain in the analysis area. This section discusses the existing conditions of the environmental media and the physical terrain as they relate to public health and safety.

Baseline air quality measurements indicate current concentrations of the criteria air pollutants are well below the NAAQS for six criteria pollutants: particulate matter (including PM$_{10}$ and PM$_{2.5}$), SO$_2$, NO$_2$, O$_3$, lead, and CO. The NAAQS are allowable concentration limits adopted by the State of Idaho into the Rules for the Control of Air Pollution in Idaho. HAPs are pollutants that are known or suspected to cause cancer, other serious health effects, or adverse environmental effects. There are currently no permitted sources of HAP emissions under Title V of the CAA in the vicinity of the analysis area. Thus, the baseline concentrations of HAPs from human-made sources are likely within regulatory limits (Trinity Consultants 2017).

Reference area soil samples collected from undisturbed mineralized and non-mineralized zones near the mine site area indicated that concentrations of antimony and arsenic are consistently higher in samples collected from mineralized zones than in samples collected in non-mineralized zones (URS 2000b; Tetra Tech 2019a, 2021a). Sampling also showed elevated levels of arsenic, antimony, and mercury in areas disturbed by legacy mining relative to reference concentrations from both non-mineralized and mineralized zones. In 2003, the Agency for Toxic Substances and Disease Registry (ATSDR) completed a Public Health Assessment for the Stibnite/Yellow Pine Mining Area (ATSDR 2003). The assessment concluded that reasonable maximum exposure concentrations of arsenic and antimony in surface soil are unlikely to result in adverse public health effects for reclamation workers and recreational users of the site.

In addition to metals, soils may have been affected by historical spills of hazardous materials (such as petroleum hydrocarbons) now buried by legacy mine waste or natural deposition of eroded material. Current baseline conditions in the analysis area include limited use, transportation, and storage of hazardous materials and petroleum substances (e.g., diesel, gasoline, jet fuel, grease, and hydraulic oils) associated with Perpetua’s existing exploration activities. The analysis area could currently be impacted by accidental releases of hazardous materials during transportation, use, or disposal of these materials.
In groundwater samples from alluvial and bedrock wells, analytes concentrations generally met regulatory
criteria except for arsenic and antimony. Arsenic and antimony are considered the key chemicals of public
health concern in groundwater in the analysis area. Highest groundwater concentrations were noted in
wells directly downgradient of the legacy disturbed areas, with concentrations generally decreasing with
distance away from those areas.

There currently are no active domestic groundwater wells used for drinking water within 15 miles of the
Operations Area Boundary. Yellow Pine’s public water system uses surface water from Boulder Creek,
which is located approximately 15 miles downstream of the Operational Area Boundary and is a tributary
to the East Fork SFSR but drains an area unaffected by prior mining activities. Because groundwater in
the SGP area does not represent a drinking water source, the ATSDR Public Health Assessment
eliminated groundwater quality from consideration as a public health concern (ATSDR 2003). Any
potential future use of existing groundwater in the SGP would likely need to incorporate appropriate
filtration or water treatment systems to remove conditions of concern due to meet regulatory criteria.

Based on surface water sampling and analyses, antimony, arsenic, and mercury are considered the key
chemicals of public health interest in surface water in the analysis area and these constituents are naturally
elevated in the region (Brown and Caldwell 2017a). The ATSDR Public Health Assessment (ATSDR
2003) evaluated potential public health risk associated with exposure to contaminants in surface water
from the mine site and concluded that contaminants in surface water would be unlikely to result in
adverse health effects for recreational users in the existing mine site (ATSDR 2003). In addition, the
assessment concluded that for recreational fishers and even for local fishers from American Indian tribes,
who have higher fish consumption rates (estimated at 2.5 times other recreational fishers), consumption of
fish harvested from surface waters in the mine site is unlikely to result in any adverse health effects.

Common physical hazards related to terrain include extremely steep slopes, rock cliffs, uneven terrain,
and fallen trees. Avalanches, rock falls, debris flows, and flash floods also present a potential hazard for
travelers, recreationists, and Forest Service and Perpetua employees, and areas that are not traditionally
flood-prone are subject to changes to the landscape caused by wildfires. Notable landslides and
avalanches were experienced in 2014, 2017, 2019, and 2022 along the SFSR Road (FR 474/50674) and
the Stibnite portion of the McCall-Stibnite Road (CR 50-412).

Superimposed on the physical terrain, the Operations Area Boundary contains some dilapidated
structures, old mining equipment, underground mine openings (all collapsed and/or closed), and altered
landscapes, such as mine pits, abandoned and reclaimed townsites, abandoned and reclaimed mine and
exploration roads, hydroelectric generating foundations, municipal dumps at various locations, the
reclaimed Hecla heap leach pad, the spent ore disposal area, and waste rock disposal areas. Because most
of these hazards are on private land, unauthorized entry is considered trespassing, but these areas are
easily accessible to the public. Efforts have been made by Perpetua to mitigate potential public safety
issues related to these features. For example, “danger” and “no-trespassing” signs are posted near pits and
waste rock disposal facilities where terrain is steep and benches could be unstable. Efforts also have been
made to render old adits inaccessible by collapsing the entrances and posting warning signs. However,
numerous hazards still exist throughout the mine site, including discarded sharp, rusted metal objects,
foundation remnants, nails, glass, and other debris (HDR 2017n).

3.18.4.2 Economics and Health

Approximately 10 percent of Valley County residents are below the poverty level, and median household and per capita incomes in Valley County are slightly higher than the statewide averages, but the percentage of people not in the labor force in Valley County is relatively high at 50.5 percent (SGP Social and Economic Conditions Specialist Report, Forest Service 2022). The current economic ability to access health care is better than the Idaho statewide average.

3.18.4.3 Public Services/Infrastructure and Health

The analysis area is remote and limited services exist; most of the remaining mining infrastructure is abandoned. Significant improvements to off-site and on-site infrastructure would be necessary to support the proposed cleanup of legacy impacts and site reclamation, exploration, mining and ore processing, and closure. The following subsections summarize the existing infrastructure conditions and services most relevant to the public health and safety analysis.

Vehicle travel on FRs and CRs in the analysis area presents health and safety risks associated with traffic incidents. The analysis area experiences harsh weather conditions that pose potential travel hazards, especially during winter, when roads become snow-covered or icy. During winter, Valley County maintains only one route from Cascade to the analysis area, which follows Warm Lake Road (CR 10-579) to the intersection with SFSR Road (FR 474), then to the East Fork Stibnite Road portion of the McCall-Stibnite Road (CR 50-412) to the village of Yellow Pine. Perpetua maintains Stibnite Road (CR 50-412) for access from the village of Yellow Pine to the SGP. All other existing routes to the mine site are not maintained (plowed or sanded) when snow-covered roads become impassable to vehicles. Currently, Warm Lake Road (CR 10-579) has the highest incident rate (eight vehicle accidents per year) out of the FRs, CRs, and state highway in the Project vicinity.

Potential public health and safety hazards associated with transmission lines are from exposure to electromagnetic fields (EMF) and shock hazards. From the Lake Fork substation, there is an existing 42-mile-long 69-kV electric transmission line that passes through Cascade and connects with a substation near Warm Lake. Electricity for Yellow Pine is currently provided by an existing 21.5-mile-long 12.5-kV electric distribution line that connects to the Warm Lake substation. Idaho Power Company’s existing transmission line runs from its Lake Fork Substation south of McCall along its existing right-of-way to the Johnson Creek Airstrip. No power is currently supplied via a transmission line to the legacy mine site.

Direct contact with exposed or downed transmission lines could result in significant electrical shock. However, incidences of downed transmission lines occur rarely, typically the result of an accident, severe weather, or natural disaster. The magnetic fields generated by transmission lines can induce currents and voltages in nearby conductive objects such as metal fences, automobiles, and metal roofs or buildings that are close to transmission lines. The induced currents in these objects can result in a small electrical shock.
or a perceptible current when contacted by humans or animals. These small shocks are a nuisance, but do not cause physiological harm (NIEHS 2002).

Perpetua currently has and uses sanitary waste handling facilities at the exploration housing facility and other facilities that were approved by Valley County, IDEQ, and Idaho Department of Health and Human Services, namely packaged sewage treatment facilities, leach fields, and a recycling program that minimizes waste and trash delivery to area landfills (Midas 2016a).

In the event of a disaster or emergency, the local government’s primary responsibility is to respond to the incident to preserve life and property. Most of the analysis area is located more than 30 miles from the nearest local emergency services as it is 68 miles from Cascade and 50 miles from McCall, the two closest communities with hospitals. The emergency transportation service stations for Life Flights are in Boise, Idaho and Ontario, Oregon and service up to a 175-mile radius area. Recently, a new helipad was added in Yellow Pine for emergency transport via Life Flight (Yellow Pine Times 2019). No urgent care or medical facilities are located close to the Operations Area Boundary or Yellow Pine; however, there is a Cascade Fire/EMS Paramedic Ambulance Substation in Yellow Pine, which allows the community to administer First Aid and Advanced Life Support (Yellow Pine Times 2018).

Fire protection is provided by fire-fighting agencies and districts in Valley County that serve the communities of Cascade, Donnelly, McCall, and Yellow Pine as well as the rural areas surrounding these towns. These fire districts provide 24-hour fire protection for businesses and residents and are mostly staffed by volunteers. In the event of a catastrophic emergency, all the fire-fighting districts, the American Red Cross Valley County Chapter, and Valley County personnel join forces to compose the Valley County Fire Working Group Collaborative. For larger scale emergencies, local officials may implement emergency statutes and ordinances and declare a local state of emergency to mobilize and commit their resources. If local governments do not have sufficient resources to handle an emergency, they can request the support of the Idaho Emergency Operations Center, which developed the Idaho Emergency Operations Plan, a statewide comprehensive plan outlining disaster emergency response (Idaho Emergency Operations Center 2017).

### 3.18.4.4 Demographics and Health

As summarized in Table 3.18-1, Valley County ranks sixth best in the state for health outcomes, based on an equal weighting of length and quality of life. Valley County ranks fourth best in the state for overall health factors, based on weighted scores for health behaviors, clinical care, social and economic factors, and the physical environment.

3.19  Recreation

3.19.1  Introduction

This section describes recreation resources, including recreation opportunities, physical facilities, access for recreation, and the setting in which recreation activities occur within the analysis area. This section also describes existing recreation uses/users and recreation-related special use permits.

3.19.2  Recreation Resources Area of Analysis

As shown in Figure 3.19-1, the analysis area for direct and indirect impacts to recreation includes PNF MA 13 (Big Creek/Stibnite) and BNF MA 21 (Lower Johnson Creek), BNF MA 20 (Upper Johnson Creek), BNF MA 19 (Warm Lake), and a portion of BNF MA 17 (North Fork Payette River). The analysis area for recreation also includes a 5-mile radius from the major SGP components, and in some locations, extends outside the MA boundaries into the adjacent FCRNRW where recreation could be affected.

3.19.3  Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to the Proposed Action and Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to Recreation. Additional descriptions of these regulations can be found in the SGP Recreation Specialist Report (Forest Service 2022m).

- **Land and Resource Management Plan:** National Forest Land and Resource Management Plans embody the provisions of the NFMA and guide natural resource management activities on NFS land. The Payette Forest Plan (Forest Service 2003a), the Boise Forest Plan (Forest Service 2010a), and the FCRNRW Plan (Forest Service 2009d) provide management prescriptions designed to realize goals for achieving desired condition for recreation and include various objectives, guidelines, and standards for this purpose.

National Forest Management Act: The NFMA directs the Forest Service through the forest planning process to provide for a variety of multiple uses, including recreation. To implement the terms of the NFMA, the Forest Service developed the ROS to ensure “a broad spectrum of dispersed and developed recreation opportunities,” which is described in further detail in Section 6.1.4, Recreation Setting (Forest Service 1982).

Executive Order 11017: As stated in the 1962 EO 11017, the Recreation Advisory Council shall include advice to the Federal agencies concerned with respect to the following aspects of outdoor recreation resources: “(1) the protection and appropriate management of scenic areas, natural wonders, primitive areas, historic sites, and recreation areas of national significance, (2) the management of Federal lands for the broadest possible recreation benefit consistent with other essential uses, (3) the management and improvement of fish and wildlife resources for recreational purposes, (4) cooperation with and assistance to the States and local governments, (5) interstate arrangements, including Federal participation where authorized and necessary, and (6) vigorous and cooperative leadership in a nationwide recreation effort.”

State of Idaho Local Land Use Planning Act (1972): As stated in Section 67-6502, the purpose of the State of Idaho Local Land Use Planning Act (1972) is, in part “to promote the health, safety, and general welfare of the people of the state of Idaho as follows: …10) to protect fish, wildlife, and recreation resources.”

Idaho Outfitters and Guides Act: The Idaho Outfitters and Guides Act (Title 36, Chapter 21, Idaho Code) requires a license as a prerequisite for conducting outfitting and guiding. Under the Act, the Idaho Outfitters and Guides Licensing Board (IOGLB) is responsible for determining the qualifications for outfitters and guides and issuing state licenses to commercial outfitters and guides in the State of Idaho.

Valley County Comprehensive Plan: The purpose of the Valley County Comprehensive Plan is to promote the health, safety, and general welfare of the people of the state of Idaho, and in part, to ensure the protection of “fish, wildlife, and recreation resources” (Valley County 2018a). The Valley County Comprehensive Plan also includes a Recreation and Open Space goal “To promote and support a viable recreation and tourism program …” (Valley County 2018a). Objectives include creating improvements for more varied recreation opportunities, promoting development of new recreation facilities when compatible with land use goals, and protecting access to public lands (Valley County 2018a).

City of Cascade Comprehensive Plan: The City of Cascade Comprehensive Plan (City of Cascade 2018) recognizes recreation and open space as management elements that set forth the community’s goals and objectives for expanded and enhanced recreational opportunities. One of the city’s goals is to “Expand recreation and open space varieties and opportunities.” The City of Cascade Comprehensive Plan recognizes the proximity of BNF recreational opportunities to residents and acknowledges that these recreational use areas are a major tourism driver.

3.19.4 Affected Environment

The analysis area is a popular area for a variety of recreation activities on both private and public lands. The village of Yellow Pine is located east of SH 55 in the analysis area, which offers limited services and had a year-round population of 32 in 2018 (Census 2018). There also is an unincorporated community in
the Big Creek/Edwardsburg area, which has residents during the summer (Forest Service 2003a). Figure 3.19-1 shows the recreation analysis area. The following sections describe the existing recreation opportunities, facilities, access, setting, use and users, and special use permits in the analysis area.

3.19.4.1 Recreation Opportunities

Summer and winter recreation opportunities are shown on Figures 6-1a through 6-1e and Figures 6-2a through 6-2e, respectively, in the Recreation Specialist Report (Forest Service 2022m). The analysis area includes over 170 miles of trails open to motorized use (Figures 6-3a and 6-3b of the Recreation Specialist Report [Forest Service 2022m]), of which over 60 percent are open to motorcycles and over 35 percent are open to vehicles 50 inches or less in width. Motorized recreation opportunities are available throughout the analysis area, including on trails in IRAs, which are predominantly in PNF MA 13 and BNF MAs 19, 20, and 21. In the winter, the Idaho Department of Parks and Recreation grooms over 96 miles of OSV trails in the analysis area. Snowmobiling is popular on these groomed OSV routes that branch off the plowed main routes through the analysis area (Figure 6-4 of the SGP Recreation Specialist Report [Forest Service 2022m]). Cross-country skiing opportunities are available in BNF MA 17 (Forest Service 2010a).

Summertime recreation opportunities such as hunting, fishing, hiking, camping, mountain biking, river recreation, and horseback riding are popular throughout the analysis area with opportunities available at both developed facilities (e.g., campgrounds and trails) and at dispersed locations (e.g., dispersed camping areas and specially designated areas). Warm Lake is a destination for water-related recreation, such as boating and swimming. Backpacking and pack trips are popular in the Big Creek area and from trailheads into the FCRNRW. Fishing opportunities are available throughout the analysis area, particularly at Johnson Creek, Warm Lake, South Fork Salmon River, and East Fork SFSR, for species such as salmon, steelhead, whitefish, and trout (Figure 6-1a through 6-1e of the SGP Recreation Specialist Report [Forest Service 2022m]).

3.19.4.2 Developed Recreation Facilities

The Warm Lake area contains most of the developed recreation facilities (apart from trailheads) in the analysis area. Forest Service campgrounds and other private recreation facilities also are located in the Big Creek and Landmark areas and along Johnson Creek Road around and south of Yellow Pine. Privately-owned recreation facilities also are located at Warm Lake and include lodges, organizational camps, and recreation residence tracts which are privately owned homes located on NFS lands. There is a lodge in the Big Creek area and one along Johnson Creek Road (Wapiti Meadow Ranch). Forest Service trailheads and trails are throughout the analysis area, several of which provide access to the FCRNRW, summarized below and described in further detail in the SGP Recreation Specialist Report (Forest Service 2022m).

Recreation facilities on NFS lands in the analysis area include 16 campgrounds, two dispersed camping areas, 28 trailheads, two interpretive sites, four lookouts/cabins, one boating site, one swimming site, and two wildlife viewing sites. The analysis area contains approximately 340 miles of developed trails, about 51 percent of which are open to motorized recreation use. Appendix A of the SGP Recreation Specialist Report (Forest Service 2022m) provides a list of the trails open to motorized vehicles, the trail length
within the analysis area, and the type of vehicles allowed on each trail. A total of 53 trails, about 49 percent of PNF and BNF developed trails (165 miles), are open for non-motorized trail use (biking, hiking, and/or horseback riding). Several of these trails are located adjacent to, or in, the FCRNRW, with trailheads located in PNF MA 13 and BNF Mas 20 and 21 providing access to trails in the FCRNRW, which are open to non-mechanized uses (e.g., hiking, backpacking, horseback riding). Appendix A of the SGP Recreation Specialist Report (Forest Service 2022m) provides a detailed list of all non-motorized trails in the analysis area.

Lake Cascade is located west of the existing IPCo transmission line corridor north and west of the BNF MA 17, accessible from a variety of roads located off SH 55 between Cascade and Donnelly. Lake Cascade State Park includes three-day use areas, two group day use areas, 12 campgrounds, and six boat ramps (Idaho Parks and Recreation 2021). The park is open year-round and provides opportunities for camping, picnicking, hiking, mountain biking, swimming, cycling, boating, sailing, windsurfing, fishing, snowshoeing, Nordic skiing, and ice fishing (Idaho Parks and Recreation 2019).

### 3.19.4.3 Recreation Access

Access to the analysis area is primarily via paved roads that lead to unpaved county and NFS roads and is summarized below. Additional detail on all access roads is provided in Appendix A of the Recreation Specialist Report (Forest Service 2022m). The main access roads (from west to east) include SH 55 and Warm Lake Road to Landmark. From Landmark, the main access roads are county-maintained gravel roads that travel north to Yellow Pine and farther to Big Creek. These roads include Johnson Creek Road and Warren-Profile Gap Road. Yellow Pine also can be reached from McCall via the county-maintained McCall-Stibnite Road.

From these main roads, connecting unpaved NFS roads provide access to NFS lands and facilities. Primary Forest Service access roads (from west to east) in the analysis area include SFSR Road, Burnt Log Road, Old Thunder Mountain Road, Meadow Creek Lookout Road, and Thunder Mountain Road. In total, there are approximately 460 miles of NFS roads in the analysis area open to all motorized vehicles year-round, and approximately 23 miles of NFS roads open to motorized vehicles seasonally (during the summer). Approximately eight miles of NFS roads are open to all vehicles during the summer (June 1 to September 15) but are open year-round to motor vehicles that are 50 inches wide or less.

In the winter (generally from November 1 to May 15), there are 96 miles of groomed OSV routes on 14 NFS roads in the analysis area. There also are approximately 4 miles of infrequently groomed OSV routes on Burnt Log Road and West Fork Creek Road. Approximately 10 miles of the SFSR Road are plowed in the winter.

In total, the analysis area also includes over 110 miles of local, county, state, and private roads that may be used for motorized recreation or to access NFS motorized recreation routes. Portions of several of these roads are plowed in the winter, allowing winter access to the analysis area. Some recreationists choose to fly into the area rather than drive. The closest public airstrips are the Johnson Creek airstrip in BNF MA 21 south of Yellow Pine and a public airstrip at Big Creek in PNF MA 13, which serve local landowners and recreationists (Forest Service 2003a).
Access and Transportation is discussed in further detail in the SGP Access and Transportation Specialist Report (Forest Service 2022k).

Recreation Setting

The management of recreation opportunities is accomplished by the Forest Service through use of the ROS, which is a system for classifying and managing recreation opportunities based on the physical setting, social setting, and managerial setting. The physical setting is defined by the type of access, the level of remoteness, and the size of the area. The social setting is defined by user density, including the amount and type of interaction between individuals (i.e., parties per day encountered). The managerial setting is defined by the level of visitor management (regulations and information), facilities and site management, and degree of naturalness.

The combination of the three settings results in six different ROS classes, described in Table 3.19-1. Because recreation access and type changes across seasons, ROS classification also may vary by season. For example, areas where motorized travel is prohibited during the summer may be open to OSV use during winter.

Table 3.19-1 Recreation Opportunity Spectrum Classes

<table>
<thead>
<tr>
<th>ROS Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primitive</td>
<td>Area characterized by essentially an unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal. The area is managed to be essentially free from evidence of human-induced restrictions and control. Motorized use in the area is not permitted.</td>
</tr>
<tr>
<td>Semi-Primitive Non-Motorized</td>
<td>Area is characterized by a natural or natural-appearing environment of moderate-to-large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present but are subtle. Motorized use is not permitted.</td>
</tr>
<tr>
<td>Semi-Primitive Motorized</td>
<td>Area is characterized by a natural or natural-appearing environment of moderate-to-large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum on-site controls and restrictions may be present but are subtle. Motorized use is permitted.</td>
</tr>
<tr>
<td>Roaded Natural</td>
<td>Area is characterized by natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidences usually harmonize with the natural environment. Interaction between users may be low to moderate, but with evidence of other users prevalent. Resource modification and utilization practices are evident but harmonize with the natural environment. Conventional motorized use is provided for in construction standards and design of facilities. Roaded Modified: A subset of Roaded Natural but includes a higher density of roads and may have management activities that dominate the landscape (Forest Service No Date).</td>
</tr>
<tr>
<td>Rural</td>
<td>Area is characterized by a substantially modified natural environment. Resource modification and utilization practices are to enhance specific recreation activities and to maintain vegetative cover and soil. Sight and sounds of humans are readily evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people. Facilities are often provided for special activities. Moderate visitor densities are provided far away from developed sites. Facilities for intensified motorized use and parking are available.</td>
</tr>
</tbody>
</table>
Urban

Area is characterized by a substantially urbanized environment, although the background may have natural-appearing elements. Renewable resources modification and utilization practices are to enhance specific recreational activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans on-site are predominant. Large numbers of users can be expected, both on-site and in nearby areas. Facilities for highly intensified motorized use and parking are available, with forms of mass transit often available to carry people throughout the site.

Source: AECOM 2020j; Forest Service 1982

### Designated ROS Classes

Figures 3.19-2 (Summer) and 3.19-3 (winter) show the existing designated ROS classes in the analysis area. The following text describes the applicable areas designated for each ROS category in the analysis area.

As discussed above, ROS classes can vary by season, which is the case in the analysis area. Designated summer ROS classes in the analysis area include Rural, Roaded Natural, Roaded Modified, Semi-Primitive Motorized, Semi-Primitive Non-Motorized, and Primitive. Designated winter ROS classes in the analysis area include the same classes as the summer, with emphasis on Semi-Primitive Motorized. Acreages of designated summer and winter ROS classes within the analysis area are listed in detail in Appendix A of the SGP Recreation Specialist Report (Forest Service 2022m), and complete descriptions of the areas within each ROS class are provided in the same report.

### ROS Physical Setting

Physical setting of a ROS class is defined by the absence or presence of human sights and sounds, physical size of an area, and the amount of environmental modification caused by human activity (Forest Service 2003b). This setting is established through three criteria: remoteness, size of area, and evidence of humans. The physical setting criteria generally correspond to ROS classes; however, ROS physical settings are not always consistent with the overall ROS class because the influence of social and managerial settings is not considered in the physical settings. The criteria for how the ROS physical settings in the area of analysis were determined and refined is further described in the SGP Recreation Specialist Report (Forest Service 2022m). In summary, ROS physical settings were determined based on motorized and non-motorized travel routes, including roads, motorized trails, and railroads. Motorized physical settings were classified as either Semi-Primitive Motorized or Roaded Natural. Non-motorized areas were classified as either Primitive or Semi-Primitive Non-Motorized based on size criteria.

The analysis area experiences a shift in ROS physical setting between summer and winter, primarily due to limited accessibility due to snow-cover. Roads and trails are obscured to recreation users and snow-cover provides overland travel opportunities that are not available during summer. Development of the winter ROS physical setting was based on the PNF and BNF winter travel management and criteria. Access is highly restricted in the analysis area and limited routes are plowed throughout the winter to permit passenger cars. The estimated summer ROS physical settings vary from the designated ROS classes in some areas. Portions of the FCRNRW that are designated as Primitive or with no ROS GIS data but located in the wilderness were determined to have a physical setting of Semi-Primitive Non-Motorized based on the adjacent physical setting and size.
In the winter, the main difference between designated ROS classes and physical settings is along Stibnite Road, Johnson Creek Road, Warm Lake Road, and SFSR Road. The areas surrounding these roads are designated as Roaded Natural and Semi-Primitive Motorized but have physical settings of Rural because these routes are plowed during the winter (unplowed portions are Semi-Primitive Motorized Groomed). Another main difference between designated ROS classes and physical settings are that many areas that are designated Roaded Modified have a physical setting of Semi-Primitive Motorized; however, the areas designated as Semi-Primitive Non-Motorized also have a physical setting of Semi-Primitive Non-Motorized in the winter. Areas with a physical setting of Primitive in the winter are similar to those described above for the summer.

3.19.4.4 Recreation Use and Users

This section discusses general recreation uses throughout the analysis area. Developed recreation use is limited to the developed recreation sites (i.e., overnight facilities) located primarily in the Warm Lake, Landmark, and Johnson Creek Road areas. Most recreation in the analysis area is dispersed use, such as hunting, fishing, hiking, backpacking, and all-terrain vehicle use, which occurs outside of these developed recreation sites. Dispersed recreation use occurs year-round in the analysis area and is a primary use of all five management areas (Forest Service 2003a, 2010a). Motorized use typically occurs on NFS trails and roads while non-motorized uses generally occur in the FCRNRW, IRAs, and on non-motorized trails.

Although there are general visitation estimates available for the PNF (Fiscal Year 2018) and BNF (Fiscal Year 2019) as part of the National Visitor Use Monitoring Program, visitor use estimates are not available for specific management areas in the PNF or BNF in the analysis area; therefore, the information below represents visits for the entire PNF and BNF and not just the analysis area. Based on estimates from the National Visitor Use Monitoring data, undeveloped areas received over 50 percent of the estimated visits in both forests. Developed area use was higher in both forests at developed day use sites than at developed overnight sites. Use at developed day use areas was about 32 percent of visits for both PNF and BNF compared to overnight use, which was about 5 percent of visits for PNF and 11 percent of visits for BNF. There were no FCRNRW visits estimated at BNF. However, at PNF, FCRNRW use accounted for about 1 percent of total visits. Overall, the BNF was estimated to receive over 2.5 times more visits than the PNF (Forest Service 2019h, 2020f, 2020g, 2021a).

Recreation is considered a major use in the Big Creek area of PNF MA 13 (Forest Service 2003a), while the “remainder of the management area receives low to moderate dispersed use associated mainly with the Big Creek/Edwardsburg area, Missouri Ridge and Monumental Creek Trails into the FCRNRW, and high mountain lakes in the upper Profile Creek drainage” (Forest Service 2003a). As noted in the Payette Forest Plan for PNF MA 13, though most use is local, “users come through the area from all over the country to use the adjacent FCRNRW, especially during big-game hunting seasons” (Forest Service 2003a).

**Hunting**

The IDFG has divided the state into 78 GMUs to aid in wildlife and hunting management. The five management areas in the analysis area overlap three IDFG GMUs: 24, 25, and 26 (Figure 3.19-1). Collectively, these GMUs were used by approximately 7,370 hunters, and 1,288 big game individuals were harvested. GMU 24 is the most used compared to GMU 25 and 26. In GMU 24, 330 deer, 336 elk, 106 black bear, one mountain lion, and three wolves were harvested, and this GMU supported approximately 4,569 hunters. Compared to all GMUs throughout Idaho, GMU 24 ranks 21st in deer hunter usage, 35th in deer harvest, 12th in elk hunter usage, 18th in elk harvest, and 9th in black bear harvest. GMU 25 and 26 were used far less with hunter usage ranking ranged from 23rd to 87th and harvest total ranking ranged from 36th to 85th depending on the species. Much of the hunting within Idaho can be done by purchasing over the counter general tags, and many species (e.g., black bear, mountain lion, and turkey) do not have tag limits. Deer (i.e., Whitetail and Mule) and elk have tag limits in some instances. For nonresident hunters, there are 195, 77, and 155 tags available in GMU 24, 25, and 26, respectively (IDFG 2021a). Elk are managed by IDFG using Elk Zones. There are two Elk Zones (i.e., McCall and Middle Fork) within the analysis area, which also contain several GMUs outside of the analysis area. The McCall Zone contains four GMUs: 19A, 23, 24, and 25, which has 816 nonresident tags. The Middle Fork Zone contains three GMUs: 20A, 26, and 27, which has 3,187 nonresident and resident tags (IDFG 2021b, c). Additionally, there are 24 outfitters and guides permitted in GMU 24, 14 permitted in GMU 25, and 37 permitted in GMU 26 (IOGLB 2020a-c). GMU 26 is primarily in the FCRNRW and includes a portion of PNF MA 13. Only BNF MA 17 is in GMU 24. BNF MAs 19, 20, and 21, and most of PNF MA 13 are in GMU 25 (Figure 3.19-1).

**Fishing**

There are many fishing opportunities throughout the analysis area in lakes, streams, rivers, and reservoirs (Figures 6-1a through 6-1e of the SGP Recreation Specialist Report [Forest Service 2022m]). The BNF river and stream fishing as well as lake and pond fishing throughout the district are noted as excellent for fishing. The IDFG oversees fishing licenses for the State of Idaho, and the analysis area falls within the IDFG Southwest Region. Fishing licenses are required and can be purchased at many local dealers or through the IDFG. There are many species of fish for harvest within the IDFG Southwest Region, details of the species available, special rules by species, as well as limits by species can be found is the Idaho Fishing Season and Rules (IDFG 2021d).

**Mountain Biking**

Mountain biking is available throughout the analysis area. Mountain biking is allowed on both open and gated forest roads, as well as trails open to non-motorized uses (Figures 6-3a and 6-3b of the SGP Recreation Specialist Report [Forest Service 2022m]). Cross-country travel via a mountain bike is not permitted (USDA BNF 2021a, USDA PNF 2021a).

**Recreational River Use**

User data for recreational river use (e.g., paddle boating, float boating, kayaking) in this area is not tracked by the Forest Service on the Payette River. Both day use and annual river passes are sold through
vendors but not all users purchase day use passes. Annual passes don’t represent actual physical presence on the rivers in days. Annual Passes admit up to four adults (people ages 15 and younger are free), so four adults and up to 70 children can be admitted for an annual pass. Any use above 75 people requires a special use permit for group activities (USDA BNF 2021b). Recreational river use is mostly in the SFSR with up to 100 permits issued. Use of the East Fork SFSR is minimal but does occur and does not require a permit.

**Horseback Riding**

Motorized and non-motorized trails throughout the district are available for use for horseback riding, but there are no trails solely dedicated to horseback riding in the BNF (USDA BNF 2021c).

**Hiking**

Numerous trails are available for day hiking and backpacking throughout the analysis area. The Forest Service provides details on the trails including location, use, distance, and terrain on interactive websites for each management area (USDA BNF 2021d, USDA PNF 2021b).

**Winter Use**

Winter use in the analysis area includes backcountry skiing/snowboarding, snowmobiling, and cross-country skiing, and snowshoeing. Winter travel routes including OSV routes and parking areas are shown on Figure 6-4 of the SGP Recreation Specialist Report (Forest Service 2022m). Neither the BNF nor PNF require permits for backcountry skiing. Idaho State Parks and Recreations passes are available for a three-day park and ski pass. Revenues from the sale of permits are utilized for trail improvements, plowing parking lots, and grooming trails (Forest Service 2022m). Snowmobiling also takes place throughout the analysis area on both groomed and ungroomed routes. Additional details on snowmobile areas and routes can be found on the BNF and PNF websites (USDA BNF 2021e, USDA PNF 2021c). As noted in Section 3.2.4.7, there are 18 avalanche paths potentially affecting 1.6 miles of the road along the proposed OSV route (DAC 2021; Figure 3.2-6). The relatively high snowfall along this route suggests that most of these paths are expected to produce D2-sized avalanches on an annual basis with potential D3 avalanches with a 10- to 30-year return period. This area is outside of current avalanche forecasting areas (Forest Service, Todd Leeds, personal communication).

**3.19.4.5 Special Recreation Use Permits**

The IOGLB issues state licenses to commercial outfitters and guides in the state of Idaho and is responsible for the administration of the Idaho Outfitters and Guides Act (Title 35, Chapter 21, Idaho Code), while the Forest Service authorizes outfitter/guide services and facilities on NFS lands.

There are 24 outfitters and guides permitted in GMU 24, 14 permitted in GMU 25, and 37 permitted in GMU 26 (IOGLB 2020a-c). GMU 26 is primarily in the FCRNRW and includes a portion of PNF MA 13. Only BNF MA 17 is in GMU 24. BNF MAs 19, 20, and 21, and most of PNF MA 13 are in GMU 25.

In all three GMUs, activities permitted by the IOGLB, which vary by outfitter, include trail rides/pack trips, mountain bike touring, backpacking, photo trips, day hikes, snowmobiling, and fishing. In GMUs
24 and 25, permitted activities also include llama packing and skiing/snowshoeing. The IOGLB also has permitted kayaking and float boating in GMUs 24 and 26. In GMU 24, wagon/sleigh rides, zip line tours, mountaineering, and power boating also are permitted.

In the three GMUs, several of the permitted outfitters also are permitted for hunting (five in GMU 24, nine in GMU 25, and 26 in GMU 26). In all three GMUs, outfitters are permitted to hunt bear, cougar, predators, wolf, elk, deer, moose, and forest grouse (species vary by outfitter).

In 2019, there were several recreation-related special use permits issued by the Forest Service for the PNF and BNF portions of the analysis area. Appendix A of the SGP Recreation Specialist Report (Forest Service 2022m) describes each of the current recreation-related special use permits that have been issued within the analysis area.

### 3.20 Scenic Resources

#### 3.20.1 Introduction

Scenic resources are the visible physical features on the landscape (e.g., land, water, vegetation, structures, and other features). Scenic resources in the area of analysis (Figure 3.20-1) are characterized as a continuous mountain landscape broken occasionally by wide valleys with flat or hilly floors. The FCRNRW is renowned for its rugged and wild character. Its designation as a wilderness makes it, at a minimum, regionally significant.

#### 3.20.2 Scenic Resources Area of Analysis

The analysis area for scenic resources is not a definitive boundary as it includes all areas where the SGP would potentially be visible to the public. The analysis area generally extends north of and along the East Fork Road segment and the Stibnite Road segment of the McCall-Stibnite Road (CR 50-412), to the east into portions of the FCRNRW, south of and along Warm Lake Road (CR 10-579), and west of Lake Cascade, and represents a 25-mile viewshed analysis area (Figure 3.20-1).

#### 3.20.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and regulations apply to the Proposed Action and Action Alternative. The following is a list of additional laws, regulations, policies, and plans at the federal, state, or local level pertaining to scenic resources. Additional descriptions of these regulations can be found in the SGP Scenic Resources Specialist Report (Forest Service 2022n).

**Forest Service:** The Payette Forest Plan and Boise Forest Plan (Forest Service 2003a, 2010a) each state that the desired condition for the scenic environment is that “scenic quality is maintained or enhanced in areas of high scenic value and other highly used recreation areas.”

**Bureau of Reclamation:** The BOR Lake Cascade Resource Management Plan (BOR 2002) includes Goals and Objectives that pertain to Scenic Resources on land that it manages.
National Environmental Policy Act: Scenic quality is a measure of the visual appeal of a parcel of land. Section 101(b) of the NEPA states that the Federal Government should use all practical means to assure aesthetically pleasing surroundings be retained for all Americans (42 USC 4331.101[b][2]).

Valley County Comprehension Plan: The purpose of the Valley County Comprehensive Plan is to promote the health, safety, and general welfare of the people of the State of Idaho, in part, to ensure that “the development on land is commensurate with the physical characteristics of the land” (Valley County 2018a). The plan contains land use goals related to scenic resources and the rural character of the landscape.

Payette River National Scenic Byway: The Payette River Scenic Byway (PRSB) Corridor Management Plan notes that the PRSB Advisory Council does not have regulatory authority and relies on Valley County and the communities along the corridor to preserve the scenic qualities of the PRSB (PRSB Advisory Council 2013). The plan does not specify guidance with regard to scenic resource management along the corridor; however, the PRSB Advisory Council “will collectively review all zoning ordinance proposals to determine if the ordinances support principal goals by preserving historic or culturally valuable assets and viewsheds, [and] limit undesired land uses within close proximity of the byway…”

City of Cascade: The City of Cascade Comprehensive Plan (City of Cascade 2017) recognizes Natural Resources as a management element that includes scenic resources as part of Goal 4.1, which states, “Protect wildlife habitat, the environmental and hydrologic functions of lands and streams, and scenic vistas.” The City of Cascade Comprehensive Plan also identifies SH 55 (PRSB) as a scenic corridor with qualities that attract visitors. It also identifies mountain ranges surrounding Cascade and the riparian corridor along Payette River as critical areas for scenic resources.

City of Donnelly: The City of Donnelly Comprehensive Plan (City of Donnelly 2014) identifies goals and policies related to Community Design. One of the city’s goals is to, “Preserve and enhance the visual appearance and unique character of the City,” and its second objective is to “Preserve and enhance the landscape views around the City.” Policy 3 states that, “Utilities shall be installed underground whenever possible to minimize visual impacts.” Goals and policies related to Public Services and Utilities includes the following objective, “Provide adequate public utility infrastructure to meet the needs of current and future residents while minimizing its visual impact.”

Forest Service Visual Management System: This system has been used since the mid-1970s to determine effects to scenery from proposed activities and is the basis of this analysis. The BNF and PNF lands have been inventoried in accordance with the Visual Management System (VMS) (Forest Service 1974b).

Combining these attributes, national forests that utilize the VMS assign a VQO to be used during project planning and implementation for the purpose of maintaining or enhancing the scenic qualities of the forest’s landscapes. VQOs are measurable standards or objectives that guide management of these lands and represent different degrees of acceptable alterations to national forest landscapes (Forest Service 1974b). The VQO categories include Preservation, Retention, Partial Retention, Modification, and Maximum modification.

---

---
In general, VQOs for highly scenic and/or highly sensitive and visible landscapes require the retention of a natural appearance yet would allow for activities with a low level of visual change. A greater degree of landscape alteration is acceptable in landscapes that are inherently less scenic, seen from a greater distance, or seen from less sensitive locations.

### 3.20.4 Affected Environment

Of the VQOs assigned to the analysis area in the Payette Forest Plan and Boise Forest Plan, approximately 42,725 acres are identified as **Preservation**, 84,073 acres are identified as **Retention**, 178,118 acres are identified as **Partial Retention**, 19,709 acres are identified as **Modification**, and 1,272 acres are identified as **Maximum Modification**. The remaining 218,945 acres within the analysis area are either private, state, or other (non-Forest Service) federal land that do not have assigned VQOs. **Figure 3.20-2** illustrates these locations in the SGP vicinity.

Data sources used to select representative Key Observation Points (KOPs) (**Figure 3.20-1**) included: viewshed analysis results, existing land use plans, recreation data, aerial photography, and Forest Plan VQO data. These data were reviewed in conjunction with the proposed SGP components to provide a comprehensive evaluation of the varied components and their potential impacts to sensitive viewer locations within the analysis area.

#### 3.20.4.1 Characteristic Landscape

Visual sensitivity pertains to the degree of concern for changes to the characteristic landscape. Sensitive use areas were identified based on the following criteria: use duration, use volume, Forest Plan sensitivity level, and scenic or special designation. Existing conditions of sensitive use areas are summarized in the text below. All areas identified as sensitive use areas in this analysis have an overall sensitivity of high or moderate.

**Travel Routes** - There are 27 roads, including highways, forest roads, and local roads, in the analysis area identified as sensitive use areas. These roads provide access for forest visitors to the two national forests, the FCRNRW, the SGP, recreation sites that include Warm Lake and the Stolle Cabin, and numerous campgrounds and trailheads, as well as serve as travel routes for the residents of the village of Yellow Pine. Most roads are seasonal and closed during winter months due to snow. However, Stibnite Road (CR 50-412), Warm Lake Road (CR 10-579), SFSR Road (FR 474/50674), and the northern portion of Johnson Creek Road (CR 10-413) are accessible to vehicles year-round. Views experienced from travel routes are transient in nature and include “superior” (views from above), “inferior” (views from below), and enclosed views; although, expanded views exist in areas where adjacent vegetation is sparse and/or low growing. Six KOPs (4, 10, 13, 14, 15, and 16) are identified along travel routes (**Figure 3.20-1**).

**Waterbodies** - There are six rivers and creeks and two lakes (Warm Lake and Lake Cascade) in the analysis area identified as sensitive use areas that are used by residents and forest visitors for motorized boating, rafting, swimming, wildlife viewing, and fishing. Near the SGP, the East Fork SFSR is accessible for dispersed recreation. Johnson Creek is accessible for water-based recreation at numerous campgrounds and dispersed campsites throughout the analysis area. Summit Lake, Caton Lake, Rainbow Lake, Curtis Lake, Black Lake, and Riordan Lake are other major bodies of water that are accessible for
dispersed recreation. Johnson Creek and Burntlog Creek are eligible for designation as WSRs (recreational and wild, respectively), and the South Fork of the Salmon River is suitable for designation as a recreational WSR. Warm Lake, Horsethief Reservoir, Lake Cascade, and the North Fork of the Payette River are also located in the analysis area and offer several recreation amenities, including campgrounds and boat launching sites. Views experienced from waterbodies include transient (from watercraft) or stationary (from the shore) and are typically inferior and enclosed to partially enclosed, meaning expansive views of adjacent scenery are not present. No KOPs were identified on or along waterbodies.

Campgrounds and Lodging - There are 16 campgrounds in the analysis area: 11 are NFS campgrounds and the remaining five campgrounds and lodging facilities are non-Forest Service facilities. Many of the campgrounds provide access to hiking trails and rivers or streams for fishing and recreational activities. There are also three dispersed campsites in the analysis area. Views experienced from campgrounds and other lodging areas are stationary and typically inferior and enclosed or partially enclosed. One KOP is identified at a campground (KOP 8) and two at dispersed camp sites (KOPs 6 and 12).

Trails and Trailheads - There are numerous trails and trailheads throughout the analysis area, although notably fewer in the northern portion. The Idaho Centennial Trail is a 900-mile state-designated trail that includes motorized and non-motorized trails on the PNF and BNF. Lookout Mountain Trailhead is a supply drop location for Idaho Centennial Trail and wilderness users. Trails traverse through the forests and cross through the analysis area providing access to the FCRNRW, lakes, rivers, lookouts, campgrounds, and other various features and provide opportunities for viewing wildlife and scenery, including the FCRNRW. Views experienced from trails are transient or stationary and include superior, inferior, enclosed, and panoramic views. Four KOPs are identified along Forest Service trails (KOPs 2, 3, 7, and 9) and two at trailheads (KOPs 5 and 11).

Other Recreational Uses - Other recreational use sites in the analysis area include interpretive sites, viewpoints, lookouts, swimming sites, picnic areas, and wildlife viewpoints. The Stibnite Interpretive site is located at the old Stibnite home foundations near the SGP and includes informational signage describing the past history of the town of Stibnite and mining in the area. There also is an interpretive site at Landmark that describes the historic ranger station established in 1924. Monumental Summit is a viewpoint offering 360-degree views of the forest and neighboring FCRNRW area. There are two lookouts: Meadow Creek Lookout and Thunderbolt Mountain Lookout. Warm Lake hosts the Billy Rice Swimming Site, and the Warm Lake Picnic Point is on a small peninsula, which offers expansive views of Warm Lake and hosts a small organization’s camp. South of Warm Lake, along SFSR Road (FR 50474), there is a point of interest for visitors to view wild salmon. Views experienced from other recreational areas are transient or stationary and include superior, inferior, enclosed, and panoramic views. One KOP is identified at Meadow Creek Lookout (KOP 1).

Residences - Residences in the analysis area were inventoried as high sensitivity, due to duration of views and concern for changes in the landscape. The village of Yellow Pine is located approximately 14 miles west of the proposed SGP at the junction of Stibnite Road (CR 50-412) and Johnson Creek Road (CR 10-413). This small community, which had a year-round population of 32 in 2018, is the nearest residential area to the SGP (Census 2018). Dispersed rural residences are generally located along Johnson Creek Road (CR 10-413) on private lands adjacent to the creek. These include Wapiti Meadows, Cox Ranch, and Bryant Ranch. The largest concentration of residential viewers on NFS lands within the analysis area...
is Warm Lake. The Warm Lake area has several seasonal residences in the Paradise Valley Summer Homes and Warm Lake Summer Homes areas. There are a few dispersed rural residences on private land off Warm Lake Highway near Scott Valley. The cities of Cascade and Donnelly are located in Long Valley near Lake Cascade and the North Fork Payette River. Several rural residences and ranches are in Long Valley, and Cascade serves as the primary logging and ranching center for residents. Several residences are located along Lake Cascade on private lands. Donnelly is at the upper end of Lake Cascade and provides access and support services to the lake and residents in the surrounding area. One KOP has been identified near the residences at Cascade (KOP 17).

3.20.4.2 Key Observation Points

The KOPs represent different types of sensitive use areas (roads, trails, recreation use areas, and residential areas) and areas where different SGP components could be visible. Existing conditions are assessed at each KOP and used to evaluate potential impacts from the SGP. Photographs taken from select KOPs are available in Appendix A of the SGP Scenic Resources Specialist Report (Forest Service 2022n).

**KOP 1: Meadow Creek Lookout**

KOP 1 represents views experienced from Meadow Creek Lookout, directed northeast. Meadow Creek Lookout is not frequently visited by the general public due to its remoteness; however, it is one of the few recreational use areas with unobstructed superior (viewed from above) views of the SGP. This location represents a moderate-sensitivity viewpoint that Forest Service staff and recreational users would see when accessing this lookout through Meadow Creek Lookout Road (FR 51290) and/or nearby Meadow Creek/Summit Trailhead and NFST 073. These areas are as level 2 sensitive use areas, which are associated with a moderate level of visual sensitivity (Forest Service 2010a).

**KOP 2: Frank Church-River of No Return Wilderness – Summit Trail (NFST 088)**

Summit Trail offers panoramic views of the Salmon River Mountains and wilderness area for the entire length of the trail between Snowshoe Summit up to Meadow Ridge. This KOP represents what moderate sensitivity recreation users (hikers, horseback riders) would see from a non-motorized trail at the edge of the wilderness. Similar to Meadow Creek Lookout, this area is not frequented by many visitors because of its remoteness; and is associated with a moderate level of sensitivity which is consistent for similar trails in this area. This trail crosses areas designated as roadless and existing views of the characteristic landscape are typically limited to dispersed recreation such as hiking or horseback riding.

**KOP 3: Frank Church-River of No Return Wilderness – Mule Hill Trail (NFST 219)**

KOP 3 at Mule Hill Trail is accessible from Meadow Creek Lookout Road (FR 51290) and provides access to the Indian Creek Trail. This viewpoint represents what high sensitivity recreation users (hikers, horseback riders) might see from a trail within the wilderness.
**KOP 4: Stibnite Road (CR 50-412)**

KOP 4 represents views experienced from the Stibnite Road portion of McCall-Stibnite Road (CR 50-412) directed east-southeast. Stibnite Road (CR 50-412) is a sensitivity level 1 travel route that provides access to the SGP through the village of Yellow Pine. This road also provides access to Thunder Mountain Road (FR 50375) through the proposed SGP, and this viewpoint represents typical views that travelers would see from Stibnite Road (CR 50-412). Previous disturbance from legacy mining activities is evident in the foreground, including light soil color contrasts from landform modifications.

**KOP 5: Hennessey Meadow Trailhead**

KOP 5 represents views from Hennessey Meadow Trailhead looking east toward the proposed transmission line corridor. Hennessey Meadow Trailhead is at the end of Horse Heaven Road (FR 416W), which is a high-clearance vehicle travel route that follows Riordan Creek. This trailhead provides access to NFST 097 which leads to Riordan Lake, a popular fishing location in the area; and NFST 233. At this location, NFST 233 traverses extremely steep terrain that is primarily accessible by experienced OHV users and may receive limited use due to this factor. This trailhead is associated with moderate sensitivity and is a typical viewpoint for motorized vehicle recreational users in the area. The past transmission line ROW corridor is evident, although structures are not present.

**KOP 6: Twin Bridges Dispersed Camping Area**

KOP 6 represents views from Twin Bridges dispersed camping area looking south toward the proposed upgraded transmission line. Twin Bridges dispersed camping area is between Johnson Creek and the existing transmission line corridor, with Johnson Creek Road (CR 10-413) immediately west of the existing transmission line. This dispersed camping area is associated with moderate visual sensitivity. This viewing location is representative of dispersed recreational viewers in the area, with views of the existing transmission line. Screening is limited, and the modifications associated with the existing ROW are co-dominant in the landscape due to the enclosed landscape setting. Human development is limited to existing roads and the transmission line ROW.

**KOP 7: Idaho Centennial Trail at Johnson Creek Road (CR 10-413) and Burntlog Creek Trail (NFST 075)**

KOP 7 represents views from the Idaho Centennial Trail (ICT) directed west toward Burnt Log Road (FR 447). The ICT follows the Burntlog Creek Trail (NFST 075) heading north to the junction of Johnson Creek Road (CR 10-413). This trail is identified as a sensitive level 1 use area and is associated with high visual sensitivity. This KOP represents a typical ICT trail user in the analysis area with views of the transmission line. Recreational viewers associated with this viewpoint currently have unobstructed views of the transmission line, primarily due to ROW vegetation clearing. Modifications near the trail are limited to existing roads and the transmission line ROW.

**KOP 8: Trout Creek Campground**

KOP 8 represents the view from Trout Creek Campground looking west. Trout Creek Campground is off Johnson Creek Road (CR 10-413) just southeast of the existing transmission line corridor. This
campground is a sensitive level 1 use area, with developed amenities including fire pits, picnic benches, and restrooms. This viewing location is representative of campers in the analysis area that would have views of the existing transmission line corridor. The existing transmission line corridor is immediately adjacent to the campsite, and screening is limited to a few rows of trees at this site. Although the transmission line structures and conductors are visually subordinate from the campground due to vegetation screening, the existing ROW clearing is visible from many locations where understory vegetation has been thinned.

**KOP 9: Boundary of the Frank Church-River of No Return Wilderness Near Pistol Lake**

KOP 9 is located approximately 3 miles east of the Burntlog Route at its closest point (Figure 3.20-1). This KOP is located approximately 0.5 miles west of Pistol Lake on a ridgeline that forms the boundary of the FCRNRW in this area. This KOP represents what dispersed recreation users (hikers, horseback riders) might see from a location at the edge of the wilderness east of the new roadway segment for the Burntlog Route. It affords superior views across drainages and ridgelines, including a burned area of the BNF. SGP features would not be visible from Pistol Lake.

**KOP 10: Burnt Log Road (FR 447)**

KOP 10 represents foreground views from Burnt Log Road (FR 447) directed southwest (Figure 3.20-1). Burnt Log Road (FR 447) is currently a high-clearance vehicle route that provides access to Snowshoe Summit Trailhead at the edge of the FCRNRW and Burntlog Creek and ends near Chilcoot Pass. This road is a sensitivity level 2 travel route and has overall moderate visual sensitivity.

**KOP 11: FCRNRW Boundary**

KOP 11 is located at the Snowshoe/Summit trailhead on the western edge of the FCRNRW boundary. Due to topography and vegetation screening, it was determined that no SGP components would be visible from this location (Forest Service 2022n); therefore, it is not carried forward in the analysis.

**KOP 12: Mud Lake Dispersed Camping Area**

KOP 12 represents views from the Mud Lake dispersed camping area looking north-northwest (KOP 12a) and south-southeast (KOP 12b) (Figure 3.20-1). Burnt Log Road (FR 447) is currently a high-clearance vehicle travel route with moderate visual sensitivity that provides access to Mud Lake dispersed camping area, just 2 miles east of Landmark.

**KOP 13: Warm Lake Road (CR 10-579) at Landmark Maintenance Facility**

KOP 13 represents views looking north from the Warm Lake Road (CR 10-579) at the proposed Landmark Maintenance Facility location (Figure 3.20-1). Warm Lake Road (CR 10-579) is a paved, passenger vehicle accessible, travel route that provides access to Landmark and Warm Lake. This is a sensitivity level 1 travel route used by summer and winter recreational visitors.
**KOP 14: Cabin Creek Road (FR 467)**

KOP 14 represents views from Cabin Creek Road (FR 467) looking north-northeast (KOP 14a) and south-southwest (KOP 14b) toward the transmission line. Cabin Creek Road (FR 467) is north of the Warm Lake area, and cuts across the Thunderbolt Mountains, terminating at Johnson Creek Road (CR 10-413) near Trout Creek Campground. This travel route is a sensitive level 2 use area and is used frequently for OHV recreation. Recreational users have views of existing transmission line corridor vegetation clearing and pole structures.

**KOP 15: South Fork Salmon River Road (FR 474) and Warm Lake Road**

KOP 15 represents views from SFSR Road (FR 474) looking southwest (KOP 15a) and northeast (KOP 15b) toward the transmission line. SFSR Road (FR 474) is a sensitive level 1 travel route near the Warm Lake recreation area. This viewpoint represents views that travelers would see from the SFSR Road (FR 474) from Rice Creek coming into Warm Lake. The existing transmission line corridor is currently visible from this KOP; views of the existing switchgear are in the foreground, unobstructed. The existing conditions around the switchgear site appear to be previously disturbed, graded, and vegetation removed or thinned. This area has been historically altered by fires, and several dead and burned trees occupy the landscape, with isolated areas of mature trees and understory vegetation.

**KOP 16: Stibnite Gold Logistics Facility**

KOP 16 represents views from Warm Lake Road (CR 10-579) looking northeast (KOP 16a) and southwest (KOP 16b) toward the SGLF. Warm Lake Road (CR 10-579) is a paved, passenger vehicle-accessible travel route that provides access to Warm Lake. This is a high-sensitivity travel route that provides access to Warm Lake from Cascade. This area in Scott Valley is primarily undisturbed with few structures on the landscape.

**KOP 17: Lake Cascade Residence**

KOP 17 represents views of residents along SH 55 near Lake Cascade looking north toward the transmission line. Residential viewers near the transmission line in Cascade are limited to a few locations near Lake Cascade and along SH 55. Views are primarily unobstructed, because the transmission line corridor is immediately adjacent to these residences or visible in the foreground. Existing modifications in this rural setting are associated with neighboring residences, agricultural or ranching facilities, distribution lines, and local roads.

### 3.21 Social and Economic Conditions

#### 3.21.1 Introduction

This section includes a discussion of existing (baseline) social and economic conditions relevant to the SGP, including population and housing, income and labor, social conditions, public services, recreation use, and government revenues.
3.21.2 Social and Economic Conditions Resources Area of Analysis

The direct and indirect effects analysis area for social and economic conditions consists of Valley County and Adams County (and associated communities), which have the potential to be directly economically affected by the SGP (Figure 3.21-1). Valley County, which contains the entire SGP area, and the associated communities of Cascade, Donnelly, McCall, and the village of Yellow Pine, has the potential to be economically affected by the SGP. Adams County and the associated towns of New Meadows, Meadow Valley, Council, and Tamarack also are included in the analysis area because of their proximity to the SGP.

3.21.3 Relevant Laws, Regulations, Policies, and Plans

Several laws and implementing regulations apply to the Proposed Action and Alternatives. The following is a list of laws, regulations, policies, and plans at the federal, state, or local level pertaining to social and economic conditions. Additional descriptions of these regulations can be found in the SGP Social and Economic Conditions Specialist Report (Forest Service 2022o).

Land and Resource Management Plan: The Payette Forest Plan (Forest Service 2003a) and the Boise Forest Plan (Forest Service 2010a) regulate the use of NFS lands for the benefit of the nation. The Payette Forest Plan and the Boise Forest Plan both have several goals and objectives to provide direction on procedural approaches and outcomes for management of NFS social and economic resources and conditions. The goals do not prescribe any specific guidance applicable for assessing socioeconomic impacts, and the specific goals and objectives for social and economic conditions are described further in the SGP Social and Economic Conditions Specialist Report (Forest Service 2022o).

General Mining Act of 1872: The Mining Law (30 USC, Chapter 2) and subsequent amendments govern the right to locate, develop, and extract mineral deposits on federal lands open to mineral entry. The Forest Service regulates locatable mineral operations on the surface of the NFS lands under regulations codified at 36 CFR 228A.

Mining and Mineral Policy Act of 1970: Through the Mining and Mineral Policy Act of 1970, Congress has stated that it is the continuing policy of the federal government, in the national interest, to foster and encourage private enterprise in the development of economically sound and stable domestic mining, minerals, and metal and mineral reclamation industries; and the orderly and economic development of domestic mineral resources, reserves, and reclamation of metals and minerals to help ensure satisfaction of industrial, security, and environmental needs. 30 U.S.C. 21a.

Forest Service Manual 1970 and Forest Service Handbook 1909.17: The FSM 1970 directs how economic and social analyses should be conducted to aid Forest Service decision making. Forest Service guidelines for socioeconomic analyses are outlined in FSH 1909.17, “Economic and Social Analysis Handbook”, which provides guidelines to be used to evaluate socioeconomic impacts that may result from policy, program, plan, or project decisions on NFS lands.

Valley County and Adams County Comprehensive Plans: Both the Valley County and Adams County comprehensive plans reaffirm the importance of natural resources to their communities’ economies (Adams County 2006; Valley County 2018a). The Valley County Comprehensive Plan includes goals and
objectives pertinent to the SGP to ensure mining remains a viable element in Valley County’s economy; to ensure new industrial activities consider long-term impacts and benefits on the local economy and environment; and, to maintain the role of the timber industry, tourism, outdoor recreation, mining, and agriculture in the local economy. Relevant goals under the Adams County Comprehensive Plan for the SGP include to provide an economically viable environment that builds and maintains a diverse base of business.

3.21.4 Affected Environment

The following section provides a summary of historic and current population and housing data, income and labor force trends, and government revenues based on the most recent data year available, as well as describes social conditions and public services in the analysis area. A complete discussion of social and economic conditions in the analysis area is provide in the SGP Social and Economic Conditions Specialist Report (Forest Service 2022o). Due to the uncertainties related to the ongoing changes in regional economic and social conditions, the data below may be inexact as it is based on prior economic conditions data and trends.

There is limited available information on use of the analysis area both by recreational visitors and Native American tribal members. As a result, the type, frequency, magnitude, and location of these users’ activities are largely unknown. Although adequate for the purposes of the socioeconomic impact analysis, limited fiscal information on Adams County’s government services and revenues was available. Neither Perpetua nor this socioeconomic analysis has been able to quantify direct revenue transfers to Valley and Adams counties resulting from the SGP’s expected future mineral license fee payments to the state of Idaho.

At the time of this reporting, some 2020 census data remains unavailable due to delays associated with the COVID-19 response; therefore, the analysis relies on the previously complete census datasets prior to 2020.

3.21.4.1 Population

Valley and Adams counties are both rural areas located in central Idaho with low population densities of 3.2 people per square mile for both counties (Census 2020). Valley County is Idaho’s fifth largest county by area (3,664 square miles) but is the 27th most populated (year-round) of the state’s 44 counties. Adams County is the 22nd largest county in Idaho by area (1,363 square miles) and one of the state’s least populated (year-round) counties (39th out of 44) (Census 2020). Valley County experiences an influx of seasonal residents, recreationists, and vacationers during both the summer and winter months which may not be accounted for in the available data (Valley County 2018a).

In 2020, Valley County had a total population of 11,746 with a median age of 49, and Adams County had a total population of 4,379 with a median age of 54. By comparison, Idaho’s corresponding total population was 1,839,106 with a median age of 36. Compared to the statewide population, both counties have a lower percentage of residents under 18 years old and a greater percentage of residents over 18 years old.

1 inch = 36 miles when printed at 11x17
Table 3.21-1 shows the populations of both counties and Idaho in 2010 and 2020. Age characteristics of both counties and Idaho in 2020 are provided in the SGP Social and Economic Conditions Specialist Report (Forest Service 2022o). Idaho was the second-fastest growing state, by population between 2010 and 2020.

The communities closest to the Operations Area Boundary include Council, New Meadows, McCall, Donnelly, Cascade, and Yellow Pine. The largest of these communities are McCall (2019 population: 3,347) and Council (2019 population: 747). Cascade had a population of 745, and New Meadows had a population of 430 in 2019 (Census 2019). Yellow Pine and Donnelly are very small communities with only 246 and 72 residents in 2019, respectively (Census 2019). Altogether, approximately half of Valley and Adams counties’ total year-round populations reside in these six communities.

#### 3.21.4.2 Housing

During the 1990s and early 2000s, Valley County experienced considerable growth in new housing units. However, since the 2008 recession, new housing construction has been relatively limited. In 2010, Valley County had an estimated total of 11,789 housing units, which increased by only 439 additional housing units by 2018 (3.7 percent increase). Similarly, from 2010 to 2018, Adams County added only 47 additional housing units (1.8 percent increase) (Census 2010, 2020).

The majority of Valley County’s housing inventory consists of vacation/seasonal second homes for out-of-county residents (Census 2010, 2018). Of Valley County’s 12,228 housing units in 2018, nearly 72 percent (8,767 units) were occasionally vacant. A total of 8,423 vacant units were reported for seasonal, recreational, or occasional use (i.e., generally second homes) with 225 non-seasonal vacant units for sale, rent, or otherwise vacant (Census 2018). Adams County reports a much lower vacancy rate of 38 percent; however, like Valley County, most vacant units are reported for seasonal, recreational, or occasional use (897 units), with 96 units available for sale, rent, or otherwise vacant.

Residential communities within the analysis area are well-established and stable. Most residents own their homes, with approximately 26 percent and 33 percent having lived in their current place of residence for 20 years or more in Valley and Adams counties, respectively (Census 2018).

The data suggest much of the housing formerly available to permanent residents has been sold to second home buyers, increasing the number of occasional housing units and decreasing the availability of housing to local residents (Highland Economics 2018). Census data on housing prices in Valley and Adams counties do not show an increase in sale price resulting from a relatively low availability of housing, as median owner-occupied housing prices for both counties have fluctuated but generally not
risen since 2010 (Census 2010, 2018; Highland Economics 2018), as shown in Table 3.21-2. Conversely, median rental rates increased in Valley County by 4.5 percent ($727 in 2010 to $760 in 2018) and in Adams County by 22.8 percent ($504 in 2010 to $619 in 2018; Census 2010, 2018b). Between 2010 and 2018, the percentage of Valley County households paying more than 30 percent of their household income on rent grew from 33.5 percent to 59.1 percent (Census 2010, 2018b). This increase indicates that the local rental market is becoming less affordable. However, the percentage of households paying more than 30 percent of their household income on rent decreased from approximately 50 percent to 39.9 percent in Adams County indicating that its local rental market has become slightly more affordable (Census 2010, 2018b).

3.21.4.3 Income and Labor

Valley County’s economy is relatively strong, and median household and per capita incomes in Valley County were slightly higher than the statewide averages, as shown in Table 3.21-3. The percentage of people not in the labor force in Valley County was also higher than the statewide average. Adams County has a comparatively weaker economy than neighboring Valley County, and median household and per capita incomes were lower than the statewide average, while its unemployment rate was nearly twice the statewide rate (Table 3.21-3).

The Idaho Department of Labor collects data on current employment by industry in each county and projects employment growth by economic region over a 10-year period (2016-2026). Both Valley and Adams counties are identified by the Idaho Department of Labor as part of the Southwestern Region, and future employment growth in the region’s professional and business services (e.g., trade, utilities, and transportation), as well as educational and health services sectors, are expected to substantially increase by 2026. No employment growth from other new major mine operations in the region’s mining and manufacturing sector over the 10-year period was forecasted (Idaho Department of Labor 2019).

Source: Census 2018; Idaho Department of Labor 2020c, 2021

1 The U.S. Census Bureau (Census) American Community Survey provides the most recent 2018 data for the population not in the labor force. The Idaho Department of Labor provides total unemployment for 2019; however, the Department does not provide data for the percentage of the population not in the labor force.

Valley County was greatly affected by the 2008 recession, but in recent years its economy has subsequently recovered. Historically, Valley County’s economy was dependent on timber extraction, but the county’s last major mill closed in 2001, and the resulting loss of 70 jobs has continued to impact the area (IDEQ 2019d). Today, tourism is a primary driver of the Valley County economy. Currently, Valley County’s highest paying jobs are in mining followed by information services, government, and education/health service sectors, while the lowest paying jobs include leisure and hospitality and other services (Idaho Department of Labor 2020b).

Adams County’s economy has recovered more slowly since the 2008 recession but has benefited from an increase in retirees relocating to the area. In 2018 the government sector jobs accounted for the largest share (31 percent) of Adams County employment. Unlike Valley County, Adams County remains more dependent on natural resources, including farming, ranching, and the timber industry (Idaho Department of Labor 2020b, 2020c). There are currently no active metal mines operating in Adams County (Idaho Department of Labor 2020c). The information sector provides Adams County’s highest paying jobs, while the tourism-industry (i.e., leisure and hospitality sector) has the lowest paying jobs (Idaho Department of Labor 2020c).

Over three quarters of Valley County workers commute less than 20 minutes to work. Adams County residents generally have much longer average commutes than Valley County or the state, with approximately 18 percent of Adams County workers commuting more than 45 minutes to work (nearly twice the statewide rate).

The Forest Service supports local economies within the analysis area through recreation, timber, energy, minerals, and livestock grazing, and counties with national forests receive funds to support schools, road maintenance, and stewardship projects. The Forest Service also contributes through its construction and maintenance of infrastructure, environmental restoration, and forest health management activities.

In 2016, Forest Service’s management and stewardship activities for the PNF supported approximately 2,010 local jobs and $73.2 million in local labor income (Forest Service 2016e). The agency’s activities...
for the BNF supported approximately 2,580 local jobs and $113.0 million in local labor income in 2016 (Forest Service 2016f).

### 3.21.4.4 Social Conditions
